Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

Mechanical Terms.

No doubt there are a great many electricians well informed as to the meaning of electrical terms and who pride themselves on their electrical knowledge, who would feel greatly offended if some one would tell them rather undiplomatically that they did not understand the English language. Yet the charge would be true.

The fact is nearly all of us are unfamiliar with a very large percentage of words in common every day use simply because they are out of our line, so to speak, and we do not notice our deficiency until they come to our attention frequently.

For example, how many of us can read a patent specification understandingly, that is to say, form anything like a correct mind's picture of the real construction and appearance of the mechanical device described? The fact is mechanical literature is just as full of appropriate terms as is electrical, and just as important, but being out of line for most of us we never bother ourselves by looking up their meaning until necessity arises.

Now there are a certain number of mechanical terms that no electrician who claims to be well informed should be unfamiliar with, especially just now, and more so in the near future, when instruction papers describing the construction and assembly of switchboards and other new telegraph equipments will find their way to managers and local electricians.

These papers will be full of such terms as lug, cam, pawl, dowel, etc.; words that have no bearing whatever on theoretical or practical telegraphy, yet have a very direct bearing on telegraph and telephone apparatus.

Take for example the word "dowel." This word refers to the "feet" under the wooden base of sounders and other flat base apparatus. The wooden "dowels" are the tubular shaped feet through which the screws go for fastening the sounder to the table or resonator. Inverted blunt nose brass upholstering tacks, when used as feet, are also called dowels.

A cam refers to a revolving wheel or shaft having an irregular periphery or set of face grooves which impart a correspondingly irregular motion or position to some piece of mechanism pressed against it by means of a compression spring or lever, or to a "roll" which follows the contour of the irregular grooves.

The word "pawl" refers to a hinged lever which rests through gravitation or spring pressure against a set of teeth for the purpose of either checking the motion of a wheel or imparting motion to it as the case may be.

The word "lug" means a projection, not necessarily of any particular shape, however. Telephone people often refer to the terminal pieces on the end of telephone jacks as lugs. The word will also apply equally well to any other projection on the framework. Reference will also be found to various kinds of springs to be used, such as retractile, compression, valve, and torsion springs.

The retractile spring used on relays is too well known to need description.

Compression springs operate in the opposite direction from retractile springs, viz.: by lengthening when the pressure is removed. They will be found on the shafts of relay magnets for the purpose of regulating the air gap, that is, for moving the magnet and coils backward or forward.

A valve spring is one in which each coil has a smaller diameter than the one below it, so that it may be compressed into a very small space. This type will be found in some types of pushbuttons, and in a modified form they are used in Morse telegraph keys for regulating the tension.

Then we have what is called a torsion spring. It is helical shaped and operates by means of a twist motion, that is, with a coiling or uncoiling action similar to that of a door spring.

Digitized by Google

Again we have terms which apply to telephone apparatus. These are probably pretty well understood by telephone operators, but most of our Morse operators are more or less unfamiliar with them. A knowledge of the particular application of such terms should be acquired at once as the days of springjacks, wedges and the present type of switchboards will soon have passed. Telephone jacks and plugs are to replace the first two mentioned, while white porcelain panels of various types, as mountings for the different apparatus, will give the new switchboard an entirely different appearance from that of the old style.

While all telephone jacks and most of the plugs look alike from the outside they are not all constructed alike within. Some have two conductors and an extra terminal connection, others have four and five terminals each which type is constructed for a special class of work. There are also solid plugs, and still another type is called an "idler."

The official instruction papers describing the manner in which the connections are to be made when installing these apparatus will call each type or part by its proper name. For instance the ball at the end of a plug is officially designated as the "tip" and the lever in the jack it makes contact with, the "tip spring." In like manner the long brass neck of the plug is called the "sleeve," and the jack conductor it connects with, the "sleeve spring." In every jack of two conductors there is always an extra spring that closes the circuit when the plug is removed. This is referred to as the "normal contact." There is also a three-conductor plug that possesses a "ring."

Space will not permit a full description of each type of plug and jack at present, but later we shall give the readers of this journal a diagram and complete description of each new type to be installed, and state the particular class of work for which each is designed as well as the boards or other locations where it will be principally used.

Telegraph and Telephone Stock Quotations.

Following are the closing quotations of telegraph and telephone stocks on the New York Stock Exchange December 26:

Amer. Telep. and Teleg. Co.	140
Mackay Companies	80⅛
" " pfd.	70
Western Union Tel. Co.	79

Personal.

Mr. Frank J. Howell of Corning, N. Y., an old time telegrapher now in other business in that city, recently spent a brief vacation in New York while en route home from the South.

Mr. Levi Wild, manager of the Butte, Mont., Western Union office, is the subject of an interesting sketch in the *Standard* of that city. He is an old timer and has grown up with the Western country.

Mr. W. N. White, of Covington, Tenn., member of the Society of the United States Military Telegraph Corps, suffered a stroke of paralysis on December 16, while on a visit to his son-in-law, Mr. F. S. Alden, at Cedar Rapids, Iowa.

Mr. W. G. Van Vleck, vice-president and general manager of the Southern Pacific Lines in Texas and Louisiana, at Houston, Tex., was formerly a telegrapher on various railroads in the West, and has had large experience in railroad work.

Major J. O. Kerbey, of Washington, D. C., an old time telegrapher, and formerly United States Consul at Para, Brazil, is the author of an interesting and well illustrated article on "Amazonia," in the November number of the "Bulletin of the Pan-American Union."

Mr. George M. Eitemiller of Detroit, Mich., the well-known telegrapher, recently received an autographed photograph from Mr. Thomas A. Edison. Mr. Eitemiller is proud over the possession of this portrait. He and Mr. Edison worked together at the key many years ago.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. E. B. Pillsbury, general superintendent, New York, has returned to his office after a trip of inspection of offices in New York State.

Mr. Minor M. Davis, superintendent of telephones of the Postal Telegraph-Cable Company, announces that his company has issued instructions to its construction department to proceed with the erection of additional heavy copper wires between all important points on the system of the company for the purpose of extending the telephonic use of the same to the independent telephone companies.

Among recent executive office visitors were Mr. J. D. McDonald, chief operator, at Boston, Mass., and C. Weydman, traffic chief, Buffalo, N. Y.

Mackay Company's Austin, Tex., Office.—The Mackay Telegraph and Cable Company opened its new office at Austin, Tex., on December 10. Mr. J. B. Sampley, formerly with the Postal Telegraph-Cable Company at Des Moines, Iowa, is manager; C. M. Thompson, day chief operator; J. K. Box, night chief operator; Miss Nora Jones, day clerk and Ivon Isbell, night clerk.

Postal Christmas Reception.

The president and executive officers of the Postal Telegraph-Cable Company held a Christmas reception in the company's headquarters in New York in the afternoon of December 22, and there was an attendance of 1,500 persons. The guests were received by Messrs. Clarence H. Mackay, president; E. J. Nally, vice-president and general manager of the Postal Telegraph-Cable Company; C. C. Adams, C. P. Bruch and G. G. Ward, second, third and fourth vice-presidents, respectively, Postal Telegraph-Cable Company and W. I. Capen, general superintendent of plant of the Postal company.

Refreshments were served, punch in one room, salads in another and cigars in a third. Everyone connected with the service in New York was present. The affair was a very delightful one and the utmost good cheer prevailed. The offices were decorated with flags, Christmas trees and flowers, and the figures "73" in electric lights greeted the guests as they entered.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr. Theo. N. Vail, president, has returned to New York after an absence of several weeks on the Pacific Coast.

Mr. C. H. Murphy, general superintendent of time service, New York, has returned from a business trip to Chicago and the West in the interest of that service.

Mr. S. M. Williams has been appointed manager of press service of this company at New York.

Mr. P. J. Casey, special agent, New York, has returned from a two-weeks' trip through the South. He was accompanied by Mrs. Casey.

Mr. C. A. Fonville has been appointed district manager, with headquarters at Montgomery, Ala., to succeed Mr. W. D. Stead, transferred to Birmingham, Ala., as district manager in that territory.

Mr. C. A. Crane, manager of the Western Union Telegraph office at St. Paul, Minn., looked after telegraph matters in connection with the recent tour of western governors. He accompanied the party on the train.

Mr. W. R. Edmondson has been appointed manager of the Jacksonville, Fla., office to succeed C. M. Holmes, resigned. Mr. Edmondson was district manager with headquarters at Jackson, Miss., at the time of his appointment.

The Chicago messenger boys of this company were given a holiday dinner by the company, December 18. After the dinner a vaudeville entertainment was provided by the Young Men's Christian Association. Several officials of the telegraph company attended the dinner.

This company has installed branch offices in all of the city and suburban stations of the Cleveland Telephone Company, Cleveland, Ohio, twenty in number.

The Western Union Telegraph Company has filed condemnation proceedings to secure the right to build its lines over the right of way of the Louisville & Nashville Railroad in the States of Kentucky, Tennessee and Mississippi, this action to be followed by similar proceedings to cover the remainder of the railroad system. The contract between the two companies will expire in August this year.

This company has advised the Public Service Commission, second district, New York, that arrangements have been completed for the delivering free of messages within corporate or municipal limits in the State of New York, including the large territory comprising Greater New York. In the outlying boroughs, however, the company will not undertake to make deliveries at any hours of the night when the local offices serving those boroughs are closed.

Mr. J. S. Calvert, district superintendent, Richmond, Va., announces the following recent appointments of managers in his district: J. W. Stephenson, at Suffolk, Va., vice T. C. Parker, transferred; T. C. Parker, at Gaffney, S. C., vice Mrs. M. B. Hardin; W. J. Terry at Aiken, S. C., vice Sam Poliakoff; E. D. House, at Spartanburg, S. C., vice C. E. Senseman; Miss E. M. McLellan at Yorkville, S. C., vice R. H. Callahan; Miss Carrie Richardson at Beaufort, S. C., vice Herbert Hall; J. P. Wimbish at Rockingham, N. C., vice Percy C. Bowling. Mrs. Hardin and Messrs. Poliakoff, Senseman, Callahan, Hall and Bowling resigned to leave the service.

General Eckert's Will Sustained.

The will of the late General Thomas T. Eckert, former president of the Western Union Telegraph Company, New York, who died on October 20, 1910, has been upheld by Surrogate Cohalan of New York. The will was contested by Mr. James Clendenin Eckert, one of the sons of the deceased, who sought to have it set aside on the ground that a fair distribution of the property had not been made. It was also charged that General Eckert was of unsound mind when he made the will of August 30,1910.

In view of the wide interest in the case and the desire of General Eckert's many friends to know the truth in the matter, we have decided to print the Surrogate's decision in full.

SURROGATE'S COURT.

By Cohalan, S.

Estate of Thomas T. Eckert—Thomas T. Eckert, the testator herein, died October 20, 1910, at Elberon, New Jersey, leaving him surviving James Clendenin Eckert and Thomas T. Eckert, Jr., his only heirs at law and next of kin. The paper propounded for probate herein as his last will and testament bears date August 30, 1910, and is signed by Thomas T. Eckert, the testator, and by Thomas C. Ennever, the attorney who drew the same, John Thom and James Miles as subscribing witnesses. The instrument devises the property known as Carlton Terrace, at Elberon, New Jersey, to Joanna Eckert, the daughter of the testator's son, James C. Eckert; devises the property known as Hearts Content, at Elberon, New Jersey, and certain coal lands in Pennsylvania, to Thomas T. Eckert, Jr.; bequeaths the sum of $5,000 each to testator's brother, William H. Eckert, and to his nieces, Mary P. Taft and Alice B. Hamlin; bequeaths the sum of $50,000 outright to his son, James Clendenin Eckert, and the sum of $100,000 to Richard G. Page, Jr., and the Central Trust Company of the City of New York, in trust, to pay the income thereof to James C. Eckert during his lifetime, the principal to be distributed among his children at his death. The residue of the testator's property, real and personal, is devised and bequeathed to Thomas T. Eckert, Jr. James C. Eckert, Thomas T. Eckert, Jr., and Richard G. Page, Jr., are named as executors. On October 31, 1910, Thomas T. Eckert, Jr., and Richard G. Page, Jr., two of the executors so named, filed in this court a petition praying for the probate of said instrument as the last will and testament of Thomas T. Eckert. James Clendenin Eckert failed to join with the other executors in the petition for probate, and on November 9, 1910, filed a verified answer praying that the probate proceedings be dismissed on the following grounds, to wit: 1. That the paper writing was not the last will and testament of Thomas T. Eckert. 2. That said alleged will was not duly executed by the testator; that he did not publish it as his last will in the presence of the witnesses whose names are subscribed thereto; that he did not request said witnesses to be witnesses thereto; that said witnesses did not sign as witnesses in his presence or in the presence of each other. 3. That on said 30th day of August, 1910, the testator was not of sound mind or memory, or mentally capable of making a will. 4. That said paper writing was not freely or voluntarily made or executed by said Thomas T. Eckert as his last will and testament, but that it was obtained, and the subscription and publication thereof were procured, by fraud and undue influence practiced on testator by Thomas T. Eckert, Jr., or some person or persons acting in concert or privity with him. 5. That said paper was not subscribed, published or attested as testator's will in conformity with the statute; and, 6, that the paper propounded was invalid as a last will and testament, and is null and void. All parties interested were duly served with citation, and the issues raised by said petition and answer came on duly to be heard before me. In considering the questions raised by the answer and by the evidence herein I shall discuss them in the following order: First. The question as to the execution of the will; second, the question of testator's mental capacity to make a will; and, third, the question of undue influence. In this connection I do not think any benefit is to be derived by quoting in detail the mass of testimony taken in this proceeding, and shall confine myself to a recital of such portions thereof as I consider essential to a fair and proper discussion of the questions at issue herein. As to the factum of the will, Thomas C. Ennever, a reputable attorney of thirty-eight years' standing at the New York Bar, the draughtsman of the will and one of the subscribing witnesses, testified that the paper offered for probate herein was drawn by him from memoranda left with him by Richard G. Page, Jr., the secretary of the testator; that he attended at Elberon, New Jersey, on August 30, 1910, at the summer residence of testator; that the will was read to the testator at testator's request in his (Ennever's) presence by Richard G. Page, Jr.; that he (Ennever) followed Page's reading of the will in a copy thereof in his possession; that the testator stated that the will as read (being the paper offered for probate herein) fully carried out his wishes, and that thereupon Page went out of the room for the other two subscribing witnesses, John Thom and James Miles, and on their arrival in the library, where General Eckert and Ennever had remained seated, testator signed the paper, declaring it to be his last will and testament, and requesting Ennever, Thom and Miles to sign same, as subscribing witnesses; that thereafter, in the presence of the other two subscribing witnesses, Thom and Miles, he (Ennever) read the attestation clause attached to the will, and thereupon Ennever, Thom and Miles signed their names as subscribing witnesses thereto. John Thom, bricklayer, another of the subscribing witnesses, testified that General Eckert signed the will in the presence of the subscribing witnesses, declared it to be his last will and testament in their presence, and requested them to sign as wit-

Digitized by Google

nesses, which they did in his presence and in the presence of each other. He also testified that before the witnesses signed their names the attestation clause was read by Mr. Ennever. James Miles, houseman, the third subscribing witness, called by the surrogate at the request of contestant, in answer to counsel for contestant stated that testator mentioned the words "Adams Street and Barber," and "asked Mr. Page about Joanna and Carlton Terrace," and Mr. Page said, "Never mind, General, that is all right;" that testator said nothing further while he was in the room; that he saw testator sign his name, also Ennever and Thom, and that he signed his own name, but stated that after the signing of testator's name no one said a word. On cross-examination by counsel for proponement he admitted that Ennever had read the attestation clause after General Eckert had signed the will. See stenographer's minutes (p. 134) the following testimony: Q. And after that was done Mr. Ennever read the attestation clause which you have just read? A. Yes. Q. Read it aloud? A. He read that clause to us. Q. Aloud? A. Yes. Q. You heard it read? A. Yes. Q. And understood it? A. I understood it, he said yes. Q. And it was true, wasn't it? A. Just as he read it there. Q. And after he had read it, then you and Ennever and Thom signed it, wasn't that it? A. Yes. And at page 135 (steno. min.) that thereafter Ennever, Thom and himself signed, and that the statements contained in the attestation clause were true—"just as he read it there" (p. 135). He also admitted that he had before the trial signed an affidavit in which he stated (see steno. min., pp. 136 and 137): Q. Now, I will read this to you: "James Miles, of 38 West 86th Street, Borough of Manhattan, City of New York, being duly sworn in the above entitled matter, and examined on behalf of the applicant to prove said will, says: 'I was acquainted with Thomas Thompson Eckert, now deceased. * * * The subscription of the name of said decedent to the instrument now shown to me and offered for probate as his last will and testament, bearing date the 30th day of August, in the year one thousand nine hundred and ten, was made by the decedent at Elberon, New Jersey, on the 30th day of August, in the year one thousand nine hundred and ten, * * * in the presence of myself and John Thom and Thomas C. Ennever, the other subscribing witnesses. * * * At the time of such subscription the said decedent declared the same instrument so subscribed by him to be his last will and testament, and I thereupon signed my name as a witness at the end of the instrument, at the request of said decedent and in his presence.'" Richard G. Page, Jr., secretary of the testator, and one of the executors named in the will, called by the surrogate at request of contestant, testified that before the signing of the will he read it to General Eckert, at Eckert's request (p. 398); that during the reading thereof General Eckert interrupted him from time to time by asking for a diaspoke about a fence; that General Eckert, in angram of property (proponent's Exhibit R), also swer to a question of Mr. Ennever, stated that he wished Thom, Miles and Ennever to act as witnesses to his will; that testator signed the will in presence of the three subscribing witnesses; that the attestation clause was read by Ennever, and also by Thom and Miles; that testator declared the paper to be his last will and testament, and the witnesses signed in the presence of testator and of each other. In view of this testimony, none of which was contradicted, the objections of the contestant as to the execution of the will are of no weight and must fall, and I feel that I must find that all the formalities of law in regard to the execution thereof were fully complied with. With regard to the mental capacity of testator to make a will, the cross-examination of Ennever brought out a somewhat lengthy conversation of General Eckert concerning a suit against a Mrs. Barber and others, and the story of an all-night search by Mrs. Eckert for a certain map or survey, which was finally found by her, and when submitted to the court settled the action in favor of General Eckert. Eckert also discussed the description of the Pennsylvania coal lands, and told Ennever of the visit of his secretary, Page, to the firm of Snyder & Zieber, of Reading, Pennsylvania, to obtain from them a proper description of that property. He also followed on a diagram the description read by Page of the property known as Hearts Content, at Elberon, and at one place in the description, where a fence was referred to, said: "That fence is not yet up. * * * What are we going to do about it?" took part in the general conversation between Ennever, Page and himself, and invited Ennever to visit his power house with Thomas T. Eckert, Jr. John Thom, another subscribing witness, also testified that the testator was of sound mind at the time of signing the will. James Miles, the third subscribing witness, who attempted to discredit the mental capacity of General Eckert, admitted on examination of proponents' counsel that he had signed the affidavit previously referred to in which he swore that testator was of sound mind and under no restraint when making his will. The secretary, Page, corroborates Ennever as to the conversations of testator at the time of the signing of the will, tells of memoranda dictated to him by the testator from which wills were to be drawn; tells of his efforts to persuade testator to be more liberal with the son Clendenin Eckert, and of testator's dissatisfaction with him because of the many unfortunate schemes in which he had invested his money; and testifies that the memoranda submitted to Ennever, from which the will was drawn, were dictated to him by General Eckert and contained a true statement of the manner in which testator finally directed that his property was to be distributed. The witness Reilly, the nurse of testator, told at length of testator's visits to No. 549 Fifth avenue, to observe the remodeling thereof; his visits to Raelly, the horse dealer; his visits to the haberdasher, the

Digitized by Google

shoemaker and hatter, from each of whom he made purchases; his insistence on obtaining goods just as he wished them, and his discussion of the political situation, all of which, in my opinion, displayed a keen mind and an intelligent interest in the matters under discussion. In fact none of the witnesses testified to anything which would lead me to believe otherwise than that testator was for one of his age a man of unusual mentality, capable in all respects to understand the nature and extent of his property and his duty toward the various members of his family, which none of his relatives ever seemed to have questioned when there was an opportunity of appealing to his generosity, but which, according to their ideas, seems only to have failed when he neglected in his will to continue toward them the bounty he had exercised in his lifetime. The testimony as to the undue influence claimed by contestant to have been exercised by the son Thomas T. Eckert, Jr., is so tenuous that I do not consider it worthy to be dignified by a discussion thereof. In fact all the evidence adduced before me can lead me to but one conclusion, and that is that the paper propounded for probate herein was the free and unrestrained act of a man mentally capable of making same, and that in the execution thereof all legal formalities were strictly complied with. In arriving at this conclusion I have utterly ignored the testimony of the alleged widow, Marie L. Davies, or Dore, whose claim, in my opinion, arose solely from the hallucinations of a disordered mind. Submit decision and decree admitting propounded paper to probate as the last will and testament of Thomas T. Eckert, and tax costs on notice.

Thomas H. Brooke, An Old War Telegrapher.

Thomas H. Brooke, the Western Union Telegraph operator at Anadarko, Okla., is one of the oldest operators in the United States, says the Anadarko "Tribune." He served as a military telegraph operator in the civil war. Early in March, 1863, Mr. Brooke reported to Captain Samuel Bruch, superintendent of the United States military telegraph corps, at Louisville, Ky., for duty as an operator. He was sent to Columbia, Ky., where the Ninth Kentucky Cavalry was then encamped. The calvary was soon withdrawn, leaving Mr. Brooke, then very young, in charge with a lineman and a secret service man or a spy, to keep up correspondence with the department at Louisville, as to the movement of General John Morgan. Often times Mr. Brooke was driven from his duty by the enemy and many times volleys of shot were fired around him. With the wire and his spy Mr. Brooke kept informed as to the moves of the enemy and kept the officers well posted as to their whereabouts. His life was risked all of the time, night and day. He was captured, made a prisoner of war, marched to a tree where preparations were made to hang him, but later it was decided to take him to camp.

He was employed at special service along the line of the Baltimore & Ohio Railway. Here is where he saw General Crook driven back by General Early. Here is also where he found that he was the only operator, railroad or commercial, in the city, as the other boys had retired beyond the city limits. Mr. Brooke carried a message to General Crook and was fired at by the enemy as he ran, but it only helped to increase his speed. Thirty years later Mr. Brooke met General Crook, who complimented him on his bravery, as the message was a very important one.

Mr. Brooke is now nearly seventy years of age. Up to this time the government has never recognized in a material way the services of the Military Telegraph Corps. A bill will be introduced at this session of Congress asking for pensions for men like Mr. Brooke. They deserve recognition.

Mr. Brooke, in spite of his years, is still young in spirit. He justly feels proud of his war record and distinctly remembers the night that the message announcing the assassination of President Lincoln was brought to him.

Western Electric Extra Dividend.

The gross sales of the Western Electric Company promise to total between $66,000,000 and $67,000,000 this year (1911). Last year, in addition to the regular quarterly dividend of 2%, the directors declared an extra dividend of 2%, and there is every reason to believe that the company will do as well by its shareholders this year, as it is in a position to make such an extra distribution.

Mr. C. F. Annett of Jerome, Idaho, a former telegrapher, writes: "I keep getting younger by reading TELEGRAPH AND TELEPHONE AGE and who knows but some day I may be induced to return to the fold. I noticed in your issue of November 16 the familiar faces of several old friends. B. E. Sunny, president of the Chicago Telephone Company, Chicago, used to send press report to me from that city when I was located in Cheyenne, Wyo., in the early seventies. Frank B. Knight, special agent for the telephone company, at Dallas, Tex., was then in Omaha for the Western Union and I worked with him frequently over the wires. Jasper N. Keller, president of the New England Telegraph and Telephone Company at Boston, was in those days a telegraph operator on the Union Pacific Railroad. Mr. Theo. N. Vail, president of the American Telephone and Telegraph Company and of the Western Union Telegraph Company, was also at that time employed in the same general locality, and is now chief of them all." Mr. Annett is now a member of the Telephone Pioneers of America.

Descriptions of inventions and latest and approved apparatus, the latest news in the telegraph and telephone fields and educational articles are the chief features of TELEGRAPH AND TELEPHONE AGE.

ADDRESS ALL COMMUNICATIONS TO
J. B. TALTAVALL, - - - Publisher
253 BROADWAY, NEW YORK.
T. R. TALTAVALL, Editor.
R. J. WEEKS, Manager Advertising Department.

CABLE ADDRESS: "Telegage," New York.
Telephone: 6657 Barclay

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

January 1, 1912.

Our New Year Greetings.

On the threshold of the New Year we extend to our friends our heartiest wishes for a happy and prosperous one. The year 1911 is now a thing of the past; it is beyond recall. The future lies before us and is yet unborn, but the present is ours, and it is our privilege to avail of the opportunities that it brings.

We are all looking to the future with the hope that it will bring us success, but as a matter of fact it will not bring us anything if we do not work in the present for what we desire. Predictions are not always reliable; there is always in them a large element of doubt, but to the optimistic mind this element approaches the vanishing point, while to the pessimist it preponderates. But we are not in the latter class; we see good and success in the next year, and in all the years to come.

In reviewing the record of the past year we find much to encourage us as to the future, and the wail of the pessimist that telegraphy is stagnant and unprogressive is not borne out by the facts. There has been improvement all along the line and what has been done in the telegraph and telephone fields during the year just closed will bring forth fruit this year. The year 1911 has truly been one of experiment in these lines and we hope the results will more than justify the effort.

Thirty Years of Successful Journalism.

Few people realize the great importance of the time element in human affairs. It is probably the most important, for without it no results could be accomplished. All the money and wisdom in the world could not bring success to any enterprise without taking time into account.

We frequently hear that this or that has stood the test of time and to the thoughtful man this means a great deal. Any business that has stood this test must necessarily be successful to some degree, for, if there were anything radically weak in its organization time would have revealed the defects; men would lose confidence in it and failure would be the inevitable result. This brings us to a consideration of the question of success. What is success? From a broad point of view success is measured by the amount of good that is exerted by one's efforts. We may be pardoned for the pride we have in the success of TELEGRAPH AND TELEPHONE AGE, viewed from this standpoint, and we can truthfully say that it has and is standing the test of time. It has labored for thirty years to bring hope and extend encouragement to those to whom it caters, and we certainly are proud of the results. The paper has assisted thousands of operators to advancement in their line of work and otherwise benefited them, both mentally and materially, and we can say without fear of contradiction that its life has so far been a successful one. What more can be said of any human enterprise?

"Be helpful" is the motto of this paper, and there is a great wealth of meaning in these two words when the duty is lived up to. In order to succeed in any undertaking that involves social and business relations one must make friends, and the faculty of doing this is one of the most desirable attainments.

It is easier to make friends than to make enemies, yet many people choose to take the latter course of action in their daily lives with the result that they are in constant trouble. TELEGRAPH AND TELEPHONE AGE has always practiced the principle of making friends, and it need hardly be said that if it had not done so it would not have survived the many years of its existence. But the friendship it has in all ranks of the great telegraph and telephone industries is its most cherished possession. It is a pleasure to work for the good of others, and with the sustaining influence of our friends, we will be able to meet our responsibilities toward them with a greater degree of success and satisfaction than ever before.

A Call to Action.

The remnant of that gallant telegraphic corps who rendered such brilliant and important service to the government during the civil war, is again appealing to Congress for the justice so long acknowledged yet thus far denied. With a bold front, though, of an average age of 70 years, the survivors are marching to the grave as heroically as they marched to battle. They are deserving of everything the government can grant them, much more than they ask. Today, under the leadership of Colonel William Bender Wilson of Holmesburg, Pa., David Homer Bates of New York and A. A. Zion, of Indianapolis, Ind., they

Digitized by Google

are conducting a campaign of appeal to Congress and to the patriotic spirit of the country for full and proper appreciation of their services. Bills have been introduced into Congress intended to give them the same rights, including pensions, which have been granted all other soldiers who served in that war. Telegraphers in all armies in the world today, in times of peace, are enjoying all the rights and privileges accorded to soldiers in other branches of the service. There is no reason why these rights and privileges should be denied our own veterans. It behooves the telegraph fraternity to take up their cause and make it their own. Wherever there is a telegraph operator in this country he or she should at once circulate petitions and send them to Congress asking that a law may be enacted to place these old and honorable members of the craft in the position they won in war. The honor and the high position in the world's advancement which telegraphy has reached demands that those who are engaged in its activities should rally to the support of this little band of military telegraphers. Superintendents, managers and operators are urged to take action at once in this worthy cause.

The Cable.

Cable Communication Restored.—Cable communication with Iceland was restored December 16.

Pacific Cable.—The new cable to be laid between Australia and New Zealand, will cost about £175,000 ($875,000), which will be taken out of the reserve fund of the Pacific Cable Board, leaving £100,000 ($500,000) still in reserve. The cable will run between Sydney and Auckland, and the New Zealand headquarters of the Board will be removed to Auckland, in order to expedite the transmission of messages.

Repairing an Atlantic Cable Under Difficulties.—The captain of the steamer *Oceanic* on a recent voyage to New York, reports passing at sea, the cable steamer *Mackay-Bennett* of the Commercial Cable Company, making repairs to a deep-sea cable in mid-ocean during a heavy storm. The *Oceanic* almost ran the cable steamer down in a dense fog. As the *Oceanic* passed the *Mackay-Bennett* the latter was shipping tremendous seas.

A small boat was out repairing the cable in the blackness of the fog and night, and the appearance of the cable ship and the small boat under these circumstances was a weird sight.

French Cable Company Adopts Reduced Press Message Rate.—The French Telegraph-Cable Company, Mr. E. C. Sweeney, traffic manager, New York, on December 15, put into effect a flat cable rate of five cents a word for deferred press dispatches between New York and London and London and New York, thus meeting the 5-cent rate for similar cablegrams by the Commercial Cable Company and the Western Union Company. Mr. Sweeney announced that a flat rate of five cents for deferred press dispatches between New York and Paris and Paris and New York was contemplated, and would be made operative as soon as the assent of the French administration had been obtained. The belief was expressed that no serious obstacle would be met in this direction.

The Cable Leases and Deferred Cable Business.

In a recent speech in London regarding the lease of the Anglo-American and Direct United States Cables to the Western Union Telegraph Company, Hon. Herbert Samuel, the British Postmaster-General said that some people feared that a monopoly might be created. He had, however, made it a condition of the Government's consent to the transfer of the landing licenses of these companies that there should be Government control in future of the cable rates across the Atlantic. He had thus been able to secure the consent of the Western Union and its allied companies to the reduction in the non-urgent press rates. The Australian Government had come into the scheme at his request, but he had not secured yet similar facilities for India and South Africa as the Eastern Telegraph Company had not been able to see its way to agree to the reductions, but the Government was pressing a scheme for a chain of wireless telegraph stations between the United Kingdom, the Mediterranean, India, Australia and New Zealand, and by that means in any event it hoped to be able to cheapen communication along the empire route.

Telegraphers of Today.

An excellent opportunity is offered to telegraph people in general to become acquainted with over 600 prominent telegraph officials and others identified with the telegraph, the railroad, the submarine cable service and press associations of the past generation, through their portraits and sketches of their careers as published in "Telegraphers of Today."

This work was issued in 1894 and includes biographical sketches of all the individuals connected with the interests mentioned at that period, many of whom have passed away from their earthly labors. The younger generation, however, will find much of interest in looking upon their portraits and reading of their achievements in life. Many of them are still alive and in harness, in the telegraph and other fields of activity.

This book, which is 11½ x 14 inches in size. was originally published at $5 per copy, but in order to close out the remaining copies we offer them at $1 per copy by express, charges collect.

Send orders to TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Russian Woman Chief of Telegraph.—Mlle. Hozlova has been appointed chief of the postal telegraph branch at Saratoff, Russia.

Course of Instruction in the Elements of Technical Telegraphy—VI.

(*Copyrighted.*)

(Continued from page 827, December 16.)

[We began in our issue for October 16 the publication of a course of instruction in technical telegraphy. The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and is divided into chapters, following one another in logical order.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases, and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.

The mathematical section which is now running will carry the student through fractions, decimals, proportion, elementary algebra, etc.]

ADDITION.

Addition in Algebra is the process of finding the simplest equivalent expression for several algebraic quantities. Such equivalent expression is called the *sum.*

Example: What is the sum of $3ax + 2ab$ and $-2ax + ab$?

Solution:

Reduce the terms to their simplest form:

$$\begin{array}{r} 3ax + 2ab \\ -2ax + ab \\ \hline ax + 3ab \end{array} \quad \text{Ans.}$$

Example: Let it be required to add together the expressions 3a, 5b, 2c.

The result is expressed thus: $3a + 5b + 2c$, and cannot be reduced to a simpler form.

For the addition of algebraic quantities we thus have the following general rule:

RULE (2). *Write down the quantities to be added so that the similar terms shall fall in the same column, and give to each term its proper sign.*

Reduce the similar terms, and after these results write, with their proper signs, the terms which cannot be reduced.

Example: What is the sum of $4ab + 8ac$ and $2ab - 7ac + d$.

Solution:

$$\begin{array}{r} 4ab + 8ac \\ 2ab - 7ac \\ + d \\ \hline 6ab + ac + d \end{array} \quad \text{Ans.}$$

NOTE. The co-efficient 1 of ac is omitted.

Example: Add together the polynomials, $3a - 2b - 4ab$, $5a - b + 2ab$, and $3ab - 3c - 2b$.

Solution:

$$\begin{array}{r} 3a - 4ab - 2b \\ 5a + 2ab - b \\ 3ab - 2b - 3c \\ \hline 8a + ab - 5b - 3c \end{array} \quad \text{Ans.}$$

SUBTRACTION.

Subtraction in Algebra is the process of finding the simplest expression for the difference between two algebraic quantities.

To subtract algebraic quantities:

RULE (3). *Write the quantity to be subtracted under that from which it is to be taken, placing the similar terms, if there are any, in the same column.*

Change the signs of all the terms of the subtrahend, and then reduce the polynomial result to its simplest form as in addition.

Example: From $6ac - 5ab + c$
Take $3ac + 3ab + 7c$

$$3ac - 8ab - 6c \quad \text{Ans.}$$

NOTE. The subtrahend with the signs changed becomes $-3ac - 3ab - 7c$, and the process is then the same as in addition.

Example: From $6am + y$ take $3am - x$

Solution:

$$\begin{array}{r} 6am + y \\ 3am \quad - x \\ \hline 3am + y + x \end{array}$$

MULTIPLICATION.

To multiply monomials:

RULE (4). *Multiply the co-efficients together for a new co-efficient. Write after this co-efficient all the letters which enter into the multiplicand and multiplier.*

Example: $8abc \times 7xy$

Multiplying the co-efficients,

$8 \times 7 = 56$.

Annexing the letters contained in multiplier and multiplicand, 56abcxy. Ans.

To multiply a polynomial by a whole number:

RULE (5). *Apply Rule 4, but multiply each term of the multiplicand by the multiplier.*

When two terms of the multiplcand and multiplier are affected with like signs the corresponding product is affected with the sign +; and when they are affected with minus signs, the product is affected with the sign —.

Example: Multiply $3a - 5b + 2c$ by $2x$

Solution:

$$\begin{array}{r} 3a - 5b + 2c \\ 2x \\ \hline 6ax - 10bx + 4cx \end{array}$$

The first term of the multiplicand being +, the product is +. The second term being — and the multiplier +, the sign of the product is —.

Example: Multiply $a - 2b - 7$ by 2

Solution:

$$\begin{array}{r} a - 2b - 7 \\ 2 \\ \hline 2a - 4b - 14 \end{array}$$

Digitized by Google

DIVISION.

To divide a polynomial by a whole number.

RULE (6). *Divide the co-efficient of each term of the polynomial by the divisor, remembering that like signs in the divisor and dividend give + in the product, and that unlike signs give —.*

Write after each new co-efficient the letters contained in the corresponding term of the dividend.

Example: Divide 16ab + 8c by 2

Solution:

$$2 \mid 16ab + 8c$$

$$8ab + 4c \quad \text{Ans.}$$

Example: Divide x + 10 by $2\frac{1}{3}$.

Solution: $2\frac{1}{3} = \frac{7}{3}$

$$\frac{x + 10}{2\frac{1}{3}} = x + 10 \text{ multiplied by } \frac{3}{7}$$

$$3 \mid 3x + 30$$

$$\frac{3}{7}x + 4\frac{2}{7} \quad \text{Ans.}$$

(*To be Continued*)

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. There is a general demand for knowledge on the quadruplex, duplex, etc., and to aid in the acquirement of such knowledge we are extending our help to students by asking questions on these subjects in each issue of our journal, so that they may be encouraged in their studies by answering them. We use as our textbook Maver and Davis' "The Quadruplex," and students should have a copy of this book at hand in order to be able to give the answers. The questions are progressive and a careful reading of the book on the points under inquiry unfolds the answers. This method of acquiring technical knowledge is a fascinating one.]

REPEATERS (*Concluded*)

In what cases is the repeating device not used?

For what purpose is one-half of a Toye repeater used in main offices?

What is the advantage of the Downer arrangement over the Toye?

In managing the Downer repeater what precautions should be taken to obtain the best results?

How should the strength of the local batteries be tested?

What may be the cause of the writing on the neutral relay being repeated back on the transmitter?

How is the trouble located?

What other forms of repeaters have been invented, and what are their functions?

What does the octuplex repeater, invented by Mr. Edwards, accomplish?

What is the feature of the multiple repeater invented by Mr. Davis?

New Books.

Practical Telephone Handbook and Guide to Telephonic Exchange. By T. S. Baldwin.

This book contains chapters on the use of the telephone, line construction, line materials, locating and correction of faults in lines and instruments, besides much other information of value to promoters, builders and managers of rural telephone lines. It is written in popular language and covers the field of telephony very thoroughly. The book is well illustrated. Price $1.00 per copy.

Operators' Wireless Telegraph and Telephone Hand Book. By Victor H. Laughter.

A complete treatise on the construction and operation of the wireless telegraph and telephone, including the rules of naval stations, codes, abbreviations, etc. The principal systems of wireless telegraphy are described and altogether this book will be found an excellent aid in the study of the art and practice of wireless telegraphy and telephony. It is profusely illustrated with views and diagrams of instruments, etc. Price $1.00 per copy.

Vest Pocket Electrical Dictionary. A practical hand book of reference containing definitions of electrical terms and phrases in use in every branch of electrical science. It is especially valuable to telegraphers and telephonists, and will be found a great aid in understanding electrical apparatus and applications of electricity in general. Price 50 cents per copy.

"Modern American Telephony in All Its Branches," edited by Arthur Bessey Smith. A very complete and up-to-date work on the subject of telephony. It has over 800 pages and nearly 600 illustrations. Price, $2.00 per copy.

Electrician's Operating and Testing Manual. By H. C. Hortsman and V. H. Tousley.

This work gives practical instructions for the management, operation and testing of the more important electrical devices now in use. It deals principally with electrical machinery and apparatus and contains much information of general value to the student of telegraphy and telephony. It is free from higher mathematics and is written in plain, easily-understood language. Liberally illustrated and substantially bound in flexible leather. Price $1.50 per copy.

These books and any others on electrical and kindred subjects, published in America or in foreign countries, may be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Mr. W. J. Camp, electrical engineer of the Canadian Pacific Railway Company's telegraph at Montreal, Que., in remitting to cover his subscription for another year, writes: "I am continually urging on the various members of our staff the advantages which might accrue to them in subscribing to the AGE to keep posted. I really consider that men in the telegraph business must read TELEGRAPH AND TELEPHONE AGE in order to keep up to date in their work."

Digitized by Google

IMPORTANT TELEGRAPH AND TELEPHONE HAPPENINGS IN 1911.

Following are summaries of the most important events of general interest that took place in the telegraphic and telephonic worlds during the year 1911. They are arranged by months, and this birdseye view of the progress of the year shows a remarkable amount of activity in both of these branches of electrical work.

JANUARY.

Loan Sharks.—The Western Union Telegraph Company inaugurated a plan to make financial loans without interest to its employes who may be in need of extra money, to be paid back in small monthly installments, the object being to get rid of the loan sharks.

Twenty-thousand Night Lettergrams in One Night.—In furtherance of their plans to secure the Panama-Pacific International Exposition in 1915, the citizens of San Francisco and other places in California and the Far West on January 23 sent about 20,000 night lettergrams to President Taft, urging him to favor their claims for the honor. The facilities of both the Western Union and Postal Telegraph-Cable Companies were taxed to the utmost.

Magnetic Club Election.—At the annual meeting of the Magnetic Club, held January 12, officers were elected.

Trial Telephone Service Illegal.—The New York Public Service Commission, Second District, notified all telephone corporations within its jurisdiction that the practice of offering trial service installations is regarded by the Commission as unlawful.

Receiver.—Judge Willson, at Philadelphia, appointed Mr. Charles E. Wilson receiver of the Continental Telephone and Telegraph Company under a bond of $100,000.

Girl Messengers in Indiana.—A bill was introduced in the Indiana legislature to prohibit the employment of girls as telegraph messengers in that State.

Montreal Telegraph Company.—The Montreal Telegraph Company held its annual meeting in Montreal, January 12.

Philadelphia Electrical Aid Society.—The twenty-third annual meeting of the Electrical Aid Society of Philadelphia was held January 10.

Serial Building Loan and Savings Institution.—At the annual election of the Serial Building Loan and Savings Institution, New York, January 17, officers and directors were elected. A dinner of the officers and directors of the institution, was held at the Astor House, January 27.

New York Public Service Commissions.—A bill was introduced in the New York Senate having for its purpose the abolition of the two existing Public Service commissions and the substitution of two corporation commissions. One of the proposed commissions is for New York City, the other commission for the territory outside New York City.

Western Union Pensions.—The Western Union Telegraph Company issued a circular letter January 23, regarding a proposed plan of pensioning employes of the company.

German Wireless Interests.—The German Operating Company for Wireless Telegraphy has been organized, with headquarters at Berlin, Germany. It is an amalgamation of all the German wireless interests and the Belgian Wireless Company of Brussels.

Wireless Institute Election.—At the meeting of the Wireless Institute held in New York, January 4, officers were elected.

Railway Telegraph Superintendents.—The quarterly meeting of the Western Division of the Association of Railway Telegraph Superintendents was held at St. Louis, Mo., January 26.

Annual Dinner of Commercial Cable Staff.—The tenth annual dinner of the staff of the Commercial Cable Company was held at New York, January 28.

New Office of Western Union at Seattle.—The new operating department of the Western Union Telegraph Company at Seattle was formally opened to the public on January 17.

Change in Value of International Volt.—On January 1 the Bureau of Standards at Washington adopted a new value for the electromotive force of the Weston normal cell.

American District Telegraph Company of New York.—The annual report of the American District Telegraph Company of New York for the calendar year of 1910 was issued.

New Atlanta Western Union Office.—The Western Union Telegraph Company moved into its new quarters in Atlanta, Ga., on January 28.

New York Telephone Earnings.—The report of the New York Telephone Company for the year ended December 31 showed revenue of $36,353,899, and expenses, including depreciation and taxes, amounting to $25,734,733, which left net earnings of $10,619,165.

Telephone Train-Dispatching Statistics.—According to the bulletin of the Interstate Commerce Commission, 41,717 miles of railway in the United States used the telephone train-dispatching system on January 1, and the telegraph was used on 175,211 miles.

FEBRUARY.

Mutual Investment Association.—The second annual meeting of the Mutual Investment Association, consisting of the employes of the Postal Telegraph-Cable Company, was held in New York, February 1.

Special Ocean Mail Service Ports.—The following ports were designated as forwarding stations for the Western Union Special Ocean Mail Service: New York, New Orleans, San Francisco, Seattle, Vancouver, St. John, N. B., and Halifax, N. S.

Dinner of Telephone Men.—The employes of the New York Telephone Company in the Westchester division held their first annual dinner in New Rochelle, N. Y., February 9.

Digitized by Google

Messenger Boy Law in New Jersey.—The New Jersey Senate passed a bill, making it a misdemeanor for telegraph companies or other employers to permit boys under eighteen years of age to deliver messages between 10 o'clock at night and 5 o'clock in the morning.

Western Union Award Upheld.—On February 20, Judge Colt, in the United States Circuit Court at Boston, confirmed the report of Mr. Everett W. Burdett as master in the suit of the Western Union Telegraph Company against the American Bell Telephone Company for an accounting on stocks received by the Bell Company as rentals and royalties for telephone licenses.

Telegraph Tolls Reduced.—The Western Union and Postal Telegraph-Cable companies notified the Public Service Commission that they would reduce telegraph rates from various points in the Adirondacks commencing June 1.

President Taft Signals to Honolulu.—President Taft pressed a telegraph key in the White House, at Washington, at 12.30 a. m., February 22, thus transmitting an impulse over the Postal Telegraph-Cable Company's line to San Francisco, a distance of about 3,700 miles thence through the Commercial Pacific Cable Company's submarine cable to Honolulu, a distance of about 2,500 miles, where the telegraph circuit was connected with a clock in the hall in which the Elks were about to open their carnival. The transmitted signal automatically lighted up the clock at 7.30 p. m., February 21, Honolulu time.

Marconi English Patent Upheld.—The English patent granted to Mr. G. Marconi relating to the principle of tuning in wireless telegraphy was upheld by an English court in a decision rendered February 21.

Meeting of the Mackay Companies.—The annual meeting of the Mackay Companies was held in Boston, February 15.

American District Telegraph Co. of New Jersey.—At the annual meeting of the American District Telegraph Company of New Jersey held in Jersey City, February 14, Messrs. Theo. N. Vail, Newcomb Carlton, William H. Baker and H. B. Thayer were chosen directors.

No Case Against Canadian Managers.—The conviction registered against certain Canadian telegraph managers for violation of the Miller Act by transmitting betting information was quashed.

New Western Union Atlantic Cable.—The new Atlantic cable of the Western Union Telegraph Company from New York (Coney Island) to England, was opened for business February 17.

Commercial Association of the Western Union.—The Greater New York Commercial Association of the Western Union Telegraph Company was organized.

Telephone Wire Through St. Gothard Tunnel.—The Swiss Government authorized the establishment of a telephone wire through the St. Gothard tunnel, enabling Berlin and Frankfort to communicate with Milan and Rome.

Taxation in Michigan.—Judge Denison, of the United States District Court at Grand Rapids, Mich., rendered a decision upholding the constitutionality of a new law providing for the taxation of telephone and telegraph companies on an ad valorem basis.

MARCH.

Western Union Day-Letter Service.—On March 1 the Western Union Telegraph Company instituted the day-letter service.

Wireless Service to Ships at Sea.—Arrangements were made whereby wireless telegrams may be received at any postal telegraph office in England for transmission to ships at sea, when such vessels have passed beyond, or have not yet entered into, the radius of operation of the Postmaster-General's coastal station.

New York Telegraphers' Aid Society Election.—The annual election of the New York Telegraphers' Aid Society took place March 27.

Washington Meeting Railway Telegraph Superintendents.—The quarterly meeting of the Eastern Division of the Association of Railway Telegraph Superintendents was held in Washington, D. C., March 22.

Wireless Telephone Company Bankrupt.—Mr. Jesse Watson was appointed receiver of the Radio-Telephone Company of New Jersey in bankruptcy proceedings filed by creditors.

Conference on Electrical Rules Disbanded.—The National Conference on Standard Electrical Rules was formally disbanded in New York on March 24.

Telepost Company Closing Offices.—The Telepost Company closed some of its way offices between Boston, Mass., and Portland, Me., because it did not pay to keep them open.

Interstate Commerce Commission Decision.—The Interstate Commerce Commission on March 20 issued rules and regulations for telegraph and telephone companies as common carriers.

Corporation Tax Law Constitutional.—The United States Supreme Court on March 13, in a decision affirmed the constitutionality of the corporation tax law imposing a tax of one per cent. on all earnings of corporations showing a net profit of over $5,000 per year.

Day-Letter Service on Texas Postal Lines.—The Postal Telegraph-Cable Company of Texas adopted the 50-word day-letter service on its lines in Texas, Arkansas, Oklahoma, Louisiana, including Joplin, Mo., and Arkansas City and Mulvane, Kan.

Meeting of Commercial News Department Officials.—Representatives of the Commercial News Department, Eastern Division of the Western Union Telegraph Company, met in New York on March 22.

Western Union Managers Meeting.—A meeting of Western Union managers in the Western section of New York state was held at Syracuse, N. Y., March 23.

Digitized by Google

United States Military Telegraph Corps.—The bill introduced in Congress purposing to place the military telegraphers on an equal footing, as to pensions and homestead rights, with those who served in other arms of the service during the Civil War, failed of consideration in common with 30,000 other bills.

Annual Meeting of American Telephone and Telegraph Company.—At the annual meeting of the American Telephone and Telegraph Company, held in New York March 28, the retiring board of directors was re-elected. The retiring officers were also re-elected.

Telegrams by Telephone.—On March 1, arrangements became effective between the Western Union Telegraph Company and the New York Telephone Company which enabled subscribers and patrons of the New York Telephone Company's system to telephone their telegrams, night letters, day letters and cable messages to Western Union offices for transmission and have the charges billed on their telephone bills.

APRIL.

German-Brazil Cable Opened for Business.—The new German cable from Emden, Germany, to Pernambuco, Brazil, by way of Monrovia, Liberia, was formally opened for business April 1.

Dinner of the Morse Electric Club.—The annual dinner of the Morse Electric Club of New York was held at the Hotel Savoy, April 6.

Prompt Transmission of Telegrams. — The United States Supreme Court has upheld as constitutional the statute of the State of Virginia prescribing a penalty upon telegraph companies for failure to transmit promptly messages filed with them.

Bell Telephone Changes.—Five of the associated companies in the middle west of the American Telephone and Telegraph Company were placed under one executive head. The companies concerned were the Michigan State Telephone Company, the Cleveland Telephone Company, the Central Union Telephone Company, the Chicago Telephone Company and the Wisconsin Telephone Company.

Telephone Bill Vetoed in Nebraska.—Governor Aldrich of Nebraska on April 12 vetoed the bill providing for placing all telephone companies in the State under the control of the State Railway Commission.

Banquet of Postal Telegraph Club of Atlanta.—The Postal Telegraph Club of Atlanta, Ga., held its second annual banquet on April 22.

Associated Press Telephone Service.—About thirty papers are receiving the Associated Press service by telephone, varying from 1,000 to 5,000 words and transmitted at regular intervals during the day or night.

Magnetic Club Spring Dinner.—The spring dinner of the Magnetic Club was held at the St. Denis Hotel, New York, April 26.

Society of Wireless Telegraph Engineers.—Officers of the Society of Wireless Telegraph Engineers were elected at the convention held in Boston.

Postal Conference.—The general superintendents of the Eastern, Western and Southern divisions were in conference with the general manager, Mr. E. J. Nally, in New York.

Annual Meeting of The Associated Press.—The annual meeting of the Associated Press was held in New York, April 25 and 26.

Philadelphia Electrical Aid Society.—The Electrical Aid Society of the City of Philadelphia held its eleventh annual entertainment on April 26.

MAY.

To Supply Typewriters.—The Western Union Telegraph Company announced that it had under consideration a plan to furnish typewriters as part of the regular equipment of offices.

Appeal to General Manager.—The general manager of the Western Union Telegraph Company invited employes to communicate with him when they have just cause for complaint of arbitrariness, discrimination, prejudice, etc.

Atlantic & Pacific Telegraph Company.—At the annual meeting of the Atlantic & Pacific Telegraph Company held in New York, the directors and officers were elected.

New England Telephone and Telegraph Annual Meeting.—At the annual meeting of the New England Telephone & Telegraph Company May 1, directors and officers were elected.

Reduction of Cable Tolls.—Postmaster-General Hon. H. Samuel announced in the British House of Commons on May 18 that he had arranged with the cable companies for a reduction of 50 per cent. on all non-code cable messages liable to be deferred not longer than twenty-four hours.

Paris-Vienna Telephone.—The telephone line between Paris and Vienna was opened for public business.

O. R. T. Convention.—The biennial convention of the Order of Railway Telegraphers was held at Toronto, Ont., May 8-17.

Hours-of-Service Law Upheld.—The United States Supreme Court on May 29 rendered a decision upholding the constitutionality of the 'Hours-of-service law for railroad employes" in the test suit instituted by the Baltimore and Ohio Railroad Company.

Wireless Officials Convicted.—A verdict of guilty of misuse of the United States mails in a scheme to defraud was returned by the jury on May 29 against Col. C. C. Wilson, president of the United Wireless Telegraph Company, New York; W. A. Diboll, treasurer; F. X. Butler, counsel; G. W. Parker, western sales agent, and W. W. Tompkins of the eastern office. Wilson was sentenced to three years in the penitentiary, Parker and Butler to two years each and Tompkins and Diboll one year each. Mr. S. S. Bogart, vice-president of the company, was sentenced to pay a fine of $2,500.

JUNE.

Taxing Commercial Cable Company in Newfoundland.—The Supreme Court of Newfoundland gave judgment in favor of the Newfoundland government in its action against the Commercial Cable Company for $16,000 yearly as landing taxes.

Continental Telegraph Company Purchased.—The Chicago, Milwaukee & Puget Sound Railway Company acquired the rights and property of the Continental Telegraph Company in North and South Dakota, Montana, Idaho and Washington.

Reduction of Telephone Rates Ordered.—The New York Public Service Commission, second district, has ordered the New York Telephone Company to make reductions in telephone charges in New York City.

Cable Station at Far Rockaway.—A plot at Far Rockaway, L. I., N. Y., was purchased by the Postal Telegraph-Cable Company. The company proposes to erect extensive buildings on the property, to be used as a receiving and transmitting station for its transatlantic cable service.

Receivers Appointed for United Wireless Company.—Messrs. Sidney Harris and Robert E. Dowling were appointed by Supreme Court Justice Cohalan as receivers for the United Wireless Telegraph Company, New York.

Conference of Pittsburgh District Managers.—A conference of district commercial managers and managers of the third district, Eastern Division, Western Union Telegraph Company, was held at Pittsburgh, Pa., June 22.

Extending Canadian Government Telegraph Lines.—The Dominion Parliament voted to build new telegraph lines and reconstruct existing lines in the northwest section of Canada.

New Telephone Stock.—At a meeting in Boston on June 20 of the directors of the American Telephone and Telegraph Company it was voted to authorize an issue of approximately $50,000,000 of new stock.

Convention of Railway Telegraph Superintendents.—The annual convention of the Association of Railway Telegraph Superintendents was held at Boston, Mass., June 26-30.

Railway Telegraph and Telephone Appliance Association.—The Railway Telegraph and Telephone Appliance Association held its annual meeting at Boston, June 27, and elected officers.

Conference of Great North Western Officials.—A conference of the principal officials and local managers of the Great North Western Telegraph Company was held at Toronto, Ont., on June 27 and 28.

Coronation Telegrams.—Press telegrams dispatched from London to the provinces and foreign countries on Coronation Day amounted to 847,000 words. On the following day, that of the Royal Progress, 370,000 words were dispatched.

JULY.

Annual Outing of French Telegraph Cable Company's Employes.—The fifth annual outing of the French Telegraph Cable Company's employes in New York was held on July 2, at College Point, L. I., N. Y.

Morse Electric Club Outing.—The summer outing of the Morse Electric Club was held at College Point, L. I., N. Y., July 8.

Contracts Signed.—The Western Union Telegraph Company and the Postal Telegraph-Cable Company of Texas signed contracts for the exchange of business.

Interstate Commerce Commission Decision.—The Interstate Commerce Commission at Washington has ruled that it has no jurisdiction over claims or damages due to alleged errors in the transmission of telegrams.

Texas Telegraph and Telephone Company Sold.—The Texas Telegraph and Telephone Company sold its 500 miles of toll lines and other physical property to the Southwestern Telegraph and Telephone Company.

AUGUST.

Turin Telegraph Tournament.—The international telegraph tournament organized in connection with the International Exposition of Labor and Manufactures, was held in Turin, Italy, August 22-26.

Age Limit Bill Vetoed.—Governor Dix of New York vetoed a bill providing that a man employed by a railroad company in the operation of telegraph, telephone or signal system shall be 21 years old and have had one year's experience.

Around the World in Sixteen and One-half Minutes.—On Sunday evening, August 20, the "New York Times" sent a telegraph message addressed to itself, around the world in order to ascertain the speed of a commercial dispatch on such a journey under normal conditions. The message was sent from the "Times" telegraph room at 7 o'clock, and at 7:16:30 it was received at the same place.

United Wireless Declared Bankrupt.—The United Wireless Telegraph Company was declared bankrupt in the United States District Court at Portland, Me., and Mr. Seldon Bacon of New York was appointed general receiver.

Mackay Company Incorporated.—The Mackay Telegraph and Cable Company was incorporated in Arkansas, with a capital stock of $10,000. The incorporators are F. W. Conger, C. T. Coffman and J. C. Marshall.

SEPTEMBER.

Convention of Municipal Electricians.—The sixteenth annual convention of the International Association of Municipal Electricians was held at Atlantic City, N. J., September 12, 13, 14 and 15.

Reunion of Old Timers.—The thirtieth annual reunion of the Old Time Telegraphers' and Historical Association and the Society of the United States Military Telegraph Corps was held at Atlantic City, N. J., September 5, 6 and 7.

Digitized by Google

Great Northwestern Election.—The annual general meeting of the shareholders of the Great Northwestern Telegraph Company was held at Toronto, Ont., September 27.

Cable Leases Approved.—At meetings of the stockholders of the Anglo-American Cable Company and the Direct United States Cable Company in London, September 29, the agreements to lease their lines to the Western Union Telegraph Company for a period of ninety-nine years was unanimously approved.

Railroads May Send Money by Telegraph.—The Interstate Commerce Commission issued an order allowing railroads to send money by telegraph to buy tickets.

OCTOBER.

Western Union Incorporations.—The Western Union Telegraph Company of Illinois was incorporated with a capital stock of $25,000. The incorporators are Roy O. West, William Rothmann and Thomas G. Deering. The Western Union Telegraph Company of Indiana has also been incorporated, with a capital of $10,000.

Western Union Annual Meeting.—The annual meeting of the stockholders of the Western Union Telegraph Company was held in New York, October 11.

Western Union Conferences.—A meeting of representative officials of the Western Union Telegraph Company was held at the Hotel Walton, Philadelphia, October 19. On October 10 a conference of the district commercial managers and managers of the third district, Eastern Division, of the Western Union Telegraph Company, was held at Pittsburgh, Pa. A conference of traffic superintendents and traffic chiefs of the large offices in the first, third, fourth and fifth districts of the Eastern Division was held at 195 Broadway, New York, on October 24 and 25.

Telegraph Monument.—The design submitted by Signor G. Romagnoli, of Bologna, Italy, for the International Telegraph Union Monument, to be erected at Berne, Switzerland, to commemorate the founding of the Union, was selected by the international jury.

NOVEMBER.

Telephone Pioneers.—The "Telephone Pioneers of America," organized an association at Boston, November 2.

Abolishes Delivery Charges.—The Western Union Telegraph Company abolished message delivery charges within city limits in all cities where such charges have been made heretofore.

Uniform Telephone Accounting.—The New York Public Service Commission, Second District, prescribed a uniform system of accounts for telephone corporations in the State of New York, to go into effect January 1, 1912.

New Building at 195 Broadway.—Announcement was made that plans are being prepared for the erection of a twenty-six story modern building on the site of the present structure at 195 Broadway, New York, to cost $3,000,000.

Annual Meeting of T. M. B. A.—The forty-fifth annual meeting of the Telegraphers' Mutual Benefit Association was held at 195 Broadway, New York, November 15.

Fall Dinner of the Magnetic Club.—The Magnetic Club held its fall dinner at the St. Denis Hotel, New York, November 15. It entertained as guests officers and members of the executive committee of the Old Time Telegraphers' and Historical Association and the Society of the United States Military Telegraph Corps and the out-of-town delegates to the annual meeting of the Telegraphers' Mutual Benefit Association.

Proposed Monument to James D. Reid.—At the fall dinner of the Magnetic Club in New York, November 15, president C. P. Bruch suggested the erection of a monument on the grave of the late James Douglas Reid, in Rochester.

Entertainment of the New York Telegraphers' Aid Society.—The annual entertainment of the New York Telegraphers' Aid Society was held in New York, November 21.

Conference in Alabama.—A conference of the managers of the larger Western Union offices in Alabama was held in Birmingham, November 17.

Boston Western Union Conference.—The second annual conference of the heads of the commercial department of the Western Union Telegraph Company in and around Boston, was held in that city November 22.

Western Union Conference in the South.—A conference of division officials and district managers was held in Atlanta, Ga., November 21, 22 and 23.

Railway Telegraph Superintendents.—A joint meeting of the eastern and western divisions of the Association of Railway Telegraph Superintendents was held in Chicago, November 23 and 24.

DECEMBER.

Reducing Telephone Rates in New York.—The new telephone tolls between Manhattan and Brooklyn boroughs, New York City, went into effect December 1.

Boston Meeting of Managers.—On December 6 a meeting of the office managers of the fifth district Eastern Division of the Western Union Telegraph Company, was held in Boston.

Deferred Cable Service Introduced by the Western Union.—Two new forms of trans-Atlantic cable service were instituted by the Western Union Telegraph Company on December 6. They are known as cable letters and week-end letters, and a deferred press service was also put into effect.

Turner Monument Dedication Postponed.—Owing to the lateness of the season it was decided to postpone the dedication exercises of the Turner monument until the end of April or the first part of May next year.

The Development and Present Composition of the Western Union Telegraph Company.*

BY E. Y. GALLAHER, AUDITOR OF THE WESTERN UNION TELEGRAPH COMPANY, NEW YORK.

Considerable progress has already been made in the operating alliance between the telegraph and telephone industries, in conformity with the policy as expressed by President Vail in his annual report for the American Telephone and Telegraph Company for the year ended December 31, 1910.

On November 30 last, the Western Union Telegraph Company was handling telegrams telephoned over the lines of twenty-four associated Bell companies. The observance of the same routine for telegrams telephoned has also been arranged with a number of railroad companies. In addition to this, approximately one hundred fifty joint offices have been established with the associated Bell companies, principally in the territories of the New England, the Southern New England, and the New York Telephone companies.

A special joint committee was recently appointed, composed of members drawn from the American Telephone and Telegraph Company, the New York Telephone Company and the Western Union Telegraph Company, representing the plant, traffic and commercial departments. The activities of this committee are directed toward experimenting in the territory of the Hudson Division of the New York Telephone Company south of Essex County in respect to the establishment of joint offices, and they have been given sufficient authority and financial assistance to carry out the scheme.

It occurred to me that in view of the contemplated extension of the relations between the telephone companies and the Western Union Company, it would be of interest to you to know something relative to the composition of the telegraph company and its plans from an accounting point of view.

ORIGIN AND DEVELOPMENT OF THE WESTERN UNION TELEGRAPH COMPANY.

The origin of the Western Union Telegraph Company is found in the organization, in 1851, of the New York and Mississippi Valley Telegraph Printing Company, with a main office at Rochester, N. Y., and a capital of $360,000, for the purpose of building a line of two wires from Buffalo to St. Louis. The capital stock was later reduced to $170,000, and only one wire erected instead of two, and this between Buffalo and Louisville.

In 1854, the company was opposed by two rival telegraph systems operating in the five states north of the Ohio River, and serious dissensions respecting rules, methods and rates were of constant occurrence.

Between 1851 and 1856 the New York and Mississippi Valley Telegraph Printing Company absorbed six other companies, and these changes had a decided tendency in effecting harmonious operating arrangements. The name of the New York and Mississippi Valley Telegraph Printing Company was changed to The Western Union Telegraph Company in 1856, and the first dividend was paid in 1857, about which time the entire telegraph interests of the country were divided in six systems, including the Western Union system.

In 1861 the Western Union extended its lines to the Pacific Coast and in 1866 the general office was moved from Rochester to New York, and practically all competitors were absorbed, giving the Western Union control of the telegraph situation, with 75,000 miles of wire. The United States Government seized what lines it required during the Civil War and at its close settled the company's damage claims by turning over the additional lines it had built, this adjustment resulting advantageously to the Western Union Company.

On July 24, 1866, Congress passed an act to the effect that any telegraph company then organized could have the right to construct and operate telegraph lines over any portion of the public domain of the United States and along military or post roads in the United States, and over and under navigable streams or waters, if such lines did not interfere with navigation or ordinary travel. In exchange for these privileges, the telegraph companies were obligated to transmit messages on account of Government business at rates to be annually fixed by the Postmaster General, such business to have priority over all other business. It was also provided that the government could at any time purchase all telegraph lines and property, the value of which would be determined by arbitrators.

In accordance with Section 4 of the act, the Western Union, in 1867, filed a written acceptance of the same with the Postmaster General.

The Supreme Court of the United States has decided that telephone companies do not come within the provisions of this act, as they are not telegraph companies, because, as the telephone industry was not in existence at the time, Congress could not have considered it. On the other hand, State courts are generally unanimous in holding that telephone companies are also telegraph companies and therefore entitled to place their lines along the post roads, etc. The marked advantage to the telegraph companies in the act of 1866 is that streets in any city are considered as post roads, so we have the right of entering to place our wires either above or underground.

Since the organization of the company under the name of The Western Union Telegraph Company, many telegraph holding companies have been absorbed or controlled, either by outright purchase, perpetual leases, or by leases of the plants for long periods, such as ninety-nine years, etc.

These holding companies had numerous subsidiary companies; and accountants who examined the books informed me that altogether, including the subsidiary companies, there were approximately four hundred taken in, but this figure is somewhat in excess of that accepted by the company's older officers.

In 1882 the Western Union leased the two ocean cables of the American Telegraph and Cable Com-

*Paper read before the Telephone and Telegraph Society of New England, Boston, Mass., December 5.

Digitized by Google

pany for a period of fifty years, and, until a year ago, a pooling arrangement existed between the Anglo American Telegraph Company, the Direct United States Cable Company and the Western Union, lessee, in respect to ocean cable traffic.

It has been the company's policy to extend its business by erecting lines along railroad rights of way, this being accomplished by contracting for the interchange of services, and, at the present time, we have something like three hundred live railroad contracts. In effect these contracts provide for the furnishing of telegraph service to railroads, either limited or unlimited, or on a half-rate basis, and, in return, the railroads allow the Western Union transportation for men and material, both on and off line, and the agreements generally include the sharing of cost relative to repairs, reconstruction and construction of lines, and the maintenance of offices and payment of joint employes.

INVESTIGATION OF COMPANY IN 1910.

It was deemed advisable, early in 1910, to have a thorough examination made of Western Union affairs by outside accountants. This investigation was directed into every branch of the company's business, except the operating; the accountants, with their force of men, being located at 195 Broadway for more than a year.

The investigation of the accountants did not include the preparation of a system of accounts and their observations along that line were only of a general nature. The main purpose in view was to present a balance sheet as of a certain date, showing the company's true financial condition, and a revenue and expense account for the year to submit to the stockholders. Concurrently with this investigation the plant records were carefully perused by a firm of outside engineers and various inquiries set on foot with the object of classifying the Western Union plant and arriving at its true value, thus affording a basis for the accountants to set up a figure representing, as nearly as possible, the actual value of the company's plant.

The balance sheet submitted by the accountants included as plant not only that constructed by the Western Union Company, but also the properties of about two hundred and forty other telegraph companies which had been merged in the system, these companies being controlled either by ownership or perpetual lease, and all outstanding liabilities to minority stockholders or bondholders were set up as part of the Western Union's capital liabilities.

REMARKS ON BALANCE SHEET OF 1911.

The total property account of the Western Union on June 30, 1911, the end of the last fiscal year, including real estate, amounted to $138,700,000. The company owns a valuable site and office building in New York and also an office building and site in the business center of Chicago. In addition to this, it has property in Chicago upon which a storehouse is located. These parcels of real estate are the most valuable the company has, but it also owns fourteen other pieces of property whereon are storehouses, pole yards, marine observatories and stations for cable business.

Under the caption "Other Securities Owned," in the balance sheet, are grouped the securities of telegraph, cable and other allied companies operated under term leases. Our agreements with these companies vary in the returns guaranteed on their capital stocks and, in some cases, we are obliged to maintain their corporate identities, and in others not. They number eight in all, and a conservative value of their securities owned is approximately $6,300,000.

The company also has shares in telegraph and cable allied companies which are not leased, these companies being ten in number, and the market value of their securities about $4,900,000.

Among the companies under term leases is the Gold and Stock Telegraph Company, of which the Western Union owns substantial control. This company, in turn, had when it was leased numerous investments of its own, among which was stock of the Metropolitan Telephone Company, the present New York Telephone Company. This stock, together with shares of the New York Telephone Company, which belonged to the Western Union Company, was sold in September, 1909, to the American Telephone and Telegraph Company for $24,300,000, and $11,060,000 of this sum, representing the interest of the Gold and Stock Company in the sale, was set up on the balance sheet under the heading "Deferred Non-interest Bearing Liability."

A large increase in the value of the New York Telephone Company stock had, of course, taken place between the time of its acquisition by the Gold and Stock Company and the Western Union, which was near the beginning of the telephone industry, and the date of the sale. Some flurry was created at the time in the value of the Gold and Stock shares when it became known that the company was interested in the sale of this stock to the American Telephone and Telegraph Company to the extent of over eleven millions of dollars, but after it was realized that this amount was not payable until 1981, seventy years from now, and that the present value of the eleven millions of dollars was only about two hundred thousand dollars, and also that the Western Union Company would participate in the distribution to the extent of its stock interest, the price subsided to the old level.

In order that the Western Union Company may have actual marketable assets on hand in 1981 to meet the deferred liability, the Executive Committee instructed that the sum of $32,600 shall be set aside and invested on the first of July of each year.

On June 30, 1911, the Western Union Company owned 204,400 miles of poles, 573,600 miles of copper wire, 913,750 miles of iron wire, with a total of 1,408,700 miles of wire and cable, and was operating 24,926 offices, of which 3,760 were independent offices, including branches. The company had some 46,000 employes, of whom 31,800 were entirely on the pay-roll of the Western Union, the remainder being for the most part joint employes with railroad companies.

Digitized by Google

The total assets were valued at $175,860,000 and the surplus was over $10,100,000. The total earnings for the last fiscal year were $35,478,000 and the net profits, before deducting interest on bonds and dividends, were $7,100,100, the sum of $2,380,000 being carried to surplus.

Practically all telegraph business in the United States is conducted by the Western Union Company and the Postal Telegraph-Cable Company and, of this business, the Western Union handles much the larger proportion.

(To be continued.)

ANSWERS TO QUESTIONS.

[In this department questions on matters of a practical character, and of general interest, will be answered. Questions intended for this department must be signed by the writer's full name—not for publication, but for identity. No attention will be paid to anonymous communications.]

(81) Q. What are the highest frequencies used in wireless telegraphy? W. A. T.

A. The United States Government has a special type high-frequency alternator in the research laboratory at Washington which has a range of frequencies of from 20,000 to 100,000 cycles per second. The rotor of this machine revolves at a speed of 20,000 revolutions per minute to generate electric waves of 100,000 cycles per second. Although the output of the machine is only 2 kw., it requires a 10-hp. motor to operate it, the air friction or adhesion of the rotor being so great.

(82) Q. Am I correct in understanding that the capacity of a storage battery decreases as the rate of discharge increases? I am advised that a battery that will furnish ten amperes for ten hours will furnish twenty amperes for only four hours, the battery receiving the same amount of charge in both cases. This is not in accordance with articles I have read on the subject. R. S. V.

A. A storage battery decreases in efficiency when it is discharged at a higher rate than the rate prescribed by the manufacturer, which is usually on the eight-hour discharge basis. A forty-ampere-hour cell, for instance, will give five amperes most efficiently for eight hours, but it will not give ten amperes in four hours, but much less, perhaps not more than eight amperes. The more rapid the rate of discharge the less the efficiency of the cell. The cause for this does not seem to be fully understood, but the losses are probably represented largely in the heat generated. Apart from this, there is great danger of damaging the plates when the cell is discharged at a rate exceeding the normal.

(83) Q. Will you please give me some information regarding the blanket insurance policy taken out by the Commercial Cable Company in favor of its employes? C. R. W.

A. Prior to the year 1905 the Commercial Cable Company had all its employes insured in the New York Life Insurance Company under the endowment plan, paying one-half of the premium, the employe paying the other half. The object was to make some provision for employes or their families in the event of death or retirement from the service. As fast as the policies mature, the proceeds are invested on behalf of the owners, in first-class securities, and held by the company until such time as they retire from the service or die, whereupon such securities are turned over to the owner or his beneficiaries. In 1905 the company also introduced a pension plan for its employes under which they receive a pension based on length of service.

(84) Q. Can you give me the sizes of wires ordinarily used expressed in vulgar fractions? H. G.

A. We assume that you desire to have the sizes expressed in practical quantities, that is, in fractions that are in every day and common use. This cannot be done, but the actual values can be approximated. Thus, for instance, the diameter of No. 0000 wire is equal to ½ inch; No. 1 = ⅓ inch; No. 2 = ¼ inch; No. 4 = 1/5 inch; No. 8 = ⅛ inch; No. 10 = 1/10 inch; No. 12 = 2/25 inch. It must be remembered that all of these values are only approximate.

Standard Oil Telegraph Lines.

In the separation of the Standard Oil Company into component parts in compliance with the decision of the United States Supreme Court, a novel situation was developed as regards the company's telegraph system. The telegraph lines run along the pipe lines of the company and hereafter will be divided into four component parts, the telegraph divisions being made to correspond with the pipe line divisions.

The company had no wires of its own in New York City, but leased several loops from the Western Union and Postal companies from its offices through the telegraph companies' offices to its private wires at Bayonne, N. J.

Over a thousand operators have been employed on the private wire system, but there will be no great change in the conditions of employment. They will hereafter work for one company, instead of for an amalgamated system. Some of the men as a result of the new order of things will have to change their places of residence. Few or none of the operators will be out of employment on account of the change.

The breaking up of the private wire system into separate divisions will compel the company to use commercial wires for its interstate business. The private system will hereafter be used strictly for pipe line business. The atmosphere is by no means clear, however.

The reorganization of the Standard Oil Company's telegraph system has given rise to some wild and grotesque reports. From the West comes the statement that the company with its present system as a nucleus is going to establish a great telegraph system that would crush the Western Union and wipe the Postal Company out of existence.

Mr. C. E. Bagley, superintendent Postal Telegraph-Cable Co., Philadelphia, Pa., in renewing his subscription for another year writes: "I have been a subscriber to the AGE since the time of its first issue. It is a most welcome visitor."

Obituary.

A. G. Hancock, a military telegrapher, died in Chicago, November 29.

Edward H. Wade, aged 38, of the Western Union force at Buffalo, N. Y., died November 29.

Clyde Crandall, wireless operator on the United States battleship *Utah*, died recently of typhoid fever.

Julian S. Eves, aged 61, of the Western Union Telegraph Company at Philadelphia, died in that city December 6.

Thos. J. Stant, aged 70, formerly an operator at Fairmount, Kan., died at Bonners Springs, Kan., December 12.

F. E. Fitzgibbons, operator for the Elmira *Advertiser*, Elmira, N. Y., died at that place December 24.

William H. Dale, formerly of the Great North Western Telegraph Company, died at Petrolia, Ont., at the age of 65 years.

Daniel Carroll Hemingray, secretary and treasurer of the Hemingray Glass Company, Covington, Ky., died on December 14.

W. C. Burrows an old time telegrapher and at one time manager of the El Paso, Tex., Postal office died at that place recently.

Frank L. Gilman, aged 53 years, a former telegrapher in Eastern cities and ex-postmaster at Laconia, N. H., died in the latter place recently.

William W. Burhans, aged 67, repeater chief of the Western Union Telegraph Company, Washington, D. C., and one of the founders of the Telegrapher's Mutual Benefit Association and a United States Military telegrapher during the civil war, died in Washington, December 13.

Mrs. Kate P. Bruch, widow of Captain Samuel Bruch and mother of Mr. Charles P. Bruch, third vice-president of the Postal Telegraph-Cable Company, New York, and of Mr. Edward B. Bruch, died at Clinton, N. J., in the afternoon of Christmas day. The funeral services were held in Canton, Ohio, where the remains were buried beside those of her husband in West Lawn Cemetery. Mrs. Bruch was highly esteemed by her many friends for her lovable, Christian character and her death will be regretted by all who knew her.

Four Deaths at New Orleans. — Within one week four members of the staff of the Western Union Telegraph office at New Orleans, La., died. They were M. S. Molony, aged 41 years, assistant manager, who died November 30; James B. Mobley, aged 62, traffic chief, died December 8; A. J. Roberts, receiving clerk, died December 4, and J. E. Elliott, manager of the cotton quotation department, died December 7. Mr. Molony was in the Western Union service for twenty-five years. Mr. Mobley was born in Allenton, Ala., and had been in the employ of the Western Union Company in New Orleans for thirty-five years.

The Late George H. Stapely.

George H. Stapely, whose death in Chicago was announced in these columns December 16, was one of the oldest and best known brokerage men in the country and leaves an estate estimated at more than a million dollars. He was born near Guelph, Ontario, forty-six years ago, and after working as an operator for the Dominion and Montreal Telegraph companies, went to Chicago in 1880. He afterwards became identified with the commission and brokerage business, and went to Cincinnati, Ohio, about 1894, where he continued to reside. Entering the employ of the O'Dell Commission Company, he rose until he became the firm's active manager and finally a partner. Later he established a business under his own name. The sudden deaths of four members of the O'Dell Company since the firm failed, is a strange coincidence. They were W. J. O'Dell, Thomas Shay, William C. Dudlev and, lastly, George H. Stapely, and they all became wealthy in the brokerage business. The late Albert S. Ayres, who was at the head of the firm's telegraph department is also dead; so the ill-luck that preceded and followed the failure has about run its course. Messrs. Dudlev and Gorman were former operators.

New Edition of Maver's Telegraphy.

Advance copies of Maver's "American Telegraphy and Encyclopedia of the Telegraph," to be known as the 1912 edition, will be ready for delivery during the coming holidays. This edition besides embodying everything of modern value in telegraph engineering and practice of the previous editions will contain fully illustrated descriptions of the new Western Union and the Postal quadruplexes, the Jones' phantoplex, the d'Humy and the Creed re-perforators, the latest improvement in fire alarm telegraph boxes, etc.

This work is used as a text-book and as a book of reference in many of the largest universities and in the large telegraph and telephone offices in this country. It contains within its covers a complete elementary treatise on electricity and magnetism, primary and storage batteries, line construction, etc. The beginner may successfully pursue his studies of these subjects by means of this book. The book is written in simple English and is practically without mathematics. No ambitious student in the telegraph or telephone ranks can afford to be without it. This work will be sent to any address, carrying charges prepaid, on receipt of price, $5.00, by TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Physiological Effects of Telephone Work.— English medical experts who have been investigating the effect of telephone work on the operators have issued a report stating that no evidence was found of injury of any of the special senses. No complaint was made of impaired hearing.

The Eiffel Tower Wireless Station.

Some interesting facts concerning the wireless station at the Eiffel tower in Paris, are given in the London "Electrical Engineer."

All the rooms for the apparatus used at the station are underground in order that the Champ de Mars may not be interfered with. There are three transmitting stations, two of which work with intermittent chargings which are ready for use in from one to two minutes. The first transmitting station is intended for small distances only, and mainly for communication with the French coasts and Algiers. It works with ten kilowatts. The transformer, resonator, spark inductor and condensers are perfectly damped with felt insulators. The second transmitting station, which is the largest if not the most modern in use, requires forty kilowatts and is fed by an alternating current of forty-two periods and 220 volts. The condenser group has a capacity of 0.7 microfarad, and consists of seven Moscicki tubes arranged in cascade. They are designed for a maximum voltage of 120,000, but 90,000 is not exceeded in normal work. The antenna is excited by a shunt. The two zinc cylinders of the exciter are full and are about ten inches in diameter and twenty inches long. Each of them is fixed on an opaline plate and one can be altered in position to permit regulation of the length of the spark. Both are rotated by an asynchronous motor. The average length of spark is about 1.5 inch.

For this equipment the antenna is a galvanized steel cable weighing 2.5 tons and 0.28 inch in diameter. Each of the six wires is 460 yards long, and is fixed at the summit of the tower by four special insulators. The earthing consists of zinc bands, having a total surface of 720 square yards. The antenna resistance is thirteen ohms, and the normal working current forty-six amperes.

The third transmitting station works with singing sparks and requires ten kilowatts with an alternating current of 600 cycles.

The spark length is about two-thirds of an inch and the current in the antenna about sixty amperes.

Besides its special military service, the Eiffel tower is employed in sending time signals and weather reports to ships within 2,500 miles distance, and also to facilitate geographical measurements.

New York Western Union Conferences.

A conference of district commercial and traffic superintendents was held at 195 Broadway, New York, on December 20, the topic for consideration and discussion being "Handling Business by Telephone." Those present were Messrs. A. G. Saylor, general superintendent; E. M. Mulford, division commercial superintendent; J. A. Hill, division traffic superintendent; M. C. Allen, division plant superintendent, all of New York; C. F. Ames, district commercial superintendent, and L. D. Wilbourn, district traffic superintendent, Boston; A. C. Terry, district commercial superintendent and W. J. Dodge, district traffic superintendent, Pittsburg, Pa.; J. W. Reed, district commercial superintendent and J. M. Creamer, district traffic superintendent, Philadelphia, Pa., and W. A. Sawyer, district commercial superintendent and Herbert Smith, district traffic superintendent, New York.

The Commercial Managers' Association of the Western Union Telegraph Company of Greater New York, held its fall meeting and dinner at the Broadway Central Hotel, on Saturday afternoon and evening, December 16.

The afternoon meeting was attended by all the district commercial managers, solicitors and local managers, at which very important matters pertaining to the commercial work in the district were discussed. Over 140 persons connected with the commercial department were present at the dinner and Mr. Newcomb Carlton, vice-president of the company, was the guest of honor.

A paper was read by Mr. John Simmonds, solicitor, who outlined the methods which he employs in inducing patrons to use the Western Union service. He was followed by Mr. F. C. Dowd, solicitor, who spoke of his work during the exploitation of the Night and Day Letters. Mr. A. Simon, solicitor, spoke of the future of the solicitor. Mr. J. W. McMahon, district commercial manager, read a paper on "Salesmanship as applied to the telegraph company," and Miss Amelia M. Prime, presented a paper relating some of the experiences that she has had in her years of service as a manager, and her efforts in soliciting telegraph business. Addresses were also made by Mr. S. M. Williams of the publicity department, Mr. J. F. Nathan, commercial superintendent, Mr. E. M. Mulford, division commercial superintendent and Mr. A. C. Kaufman, commercial agent of the eastern division.

Mr. Carlton in the course of his remarks stated that he had attended a great many dinners and had listened to many after-dinner speeches, but that at none had he heard such entertaining and instructive talk. He complimented the association very highly and said that he would convey to President Vail, at the first opportunity, the good impressions that he had gained from his intercourse with those present.

Mr. P. J. Casey, president of the association, acted as toastmaster and introduced the speakers in his customary versatile manner.

Municipal Electricians.

Police Telegraph for Binghamton.—A police telegraph system has been recommended for Binghamton, N. Y.

Brooklyn's Fire Alarm System Assailed.—The National Board of Fire Underwriters, which has been examining the fire alarm system in Brooklyn, N. Y., reports that it is "dangerously unreliable and

Digitized by Google

inadequate," and has been "extended and maintained without any well-defined plan, and maintenance in the past has been poor."

Modern Fire Alarm Station.—The fire alarm and police telegraph headquarters at Oakland, Cal., are housed in a handsome fireproof structure erected especially for the purpose, and the equipment is complete and modern in every detail. The equipment includes a 100 local 20 trunk private exchange telephone switchboard (utilized to half its capacity at present), a large storage battery plant, etc.

Radio-Telegraphy.

Telefunken Wireless Station on Long Island.—The Telefunken Wireless Telegraph Company is erecting a plant at West Sayville, L. I. A 480-foot tower is being built.

Coltano Wireless Station.—The Coltano, Italy, wireless station which was recently opened under the direction of Mr. Wm. Marconi, has an available power of 1000 kw. and a wave length of 1200 meters.

United Wireless Affairs.—Stockholders of the United Wireless Telegraph Company, now in the hands of receivers, held a meeting in New York, December 15, to devise ways and means to effect a reorganization. A committee was appointed to take the matter up.

Controlling Torpedoes by Wireless.—Mr. John Hays Hammond, Jr., son of the well-known mining engineer, has devised a means of wireless control of submarine torpedoes propelled by any power. He carried on experiments at Gloucester, Mass., all last summer.

Long Distance Wireless.—The naval wireless station at Newport, R. I., recently picked up messages sent by the Mare Island, Cal., station to the Key West, Fla., station. The wireless set at the Newport torpedo station is a Telefunken 5 kw. variometer set, and the one at Mare Island is exactly similar.

Wireless in Brazil Ordered Discontinued.—The Brazilian government has notified the American Amazon Wireless Telegraph and Telephone Company, which was licensed last April to operate its system in the Amazon country, that it must discontinue operations, on the ground that the Government at some future time might desire to operate a wireless system of its own.

First Violation of Wireless Ship Act.—The first prosecution for violation of the federal wireless ship act is pending in the United States District Court at Baltimore, Md. The steamer *Templemore* took a large number of Republican politicians across to England and Ireland some months ago and was not provided with wireless apparatus. The law requires that any steamer carrying more than fifty passengers and sailing more than 200 miles from the coast shall be provided with a wireless outfit.

Efficiency of "Earths" in Radio-Telegraphy.—In an article in *Electrical World*, Mr. Charles A. Culver gives an account of some experimental investigations of the variation in efficiency with the size and position of earth wires. He concludes that the disposition of the earth connection in arranging a system for radiating or intercepting electromagnetic waves is of prime importance. These preliminary tests were carried out across both land and water. While the results were not wholly concordant, the data appear to warrant a thorough and systematic investigation of the relative efficiency of various earth connections.

Wireless Distress Signals.—Mr. W. J. Bryan recently suggested that two wireless operators be employed on passenger steamers so that the service would be available at any time during the twenty-four hours. Mr. Louis W. Austin, of the United States Naval radio-telegraphic laboratory at Washington, D. C., suggests that the captains of steamers detail some one to wear the head telephones while the operator is off duty, and that the distress signal be made "S S S," for instance. Any one not familiar with the telegraphic code, could recognize the three dots repeated, and in this way distress signals would not be lost on account of the operator being off duty.

Wireless Control of Boats.

There was exhibited on the river Danube at Vienna, Austria, recently, a boat which was controlled by wireless from the bank, without any person being on board. The boat carried a storage battery which furnished the motive power, the "system" or invention consisting in the adaptation of wireless electric waves of different lengths to the control of the motive power, steering gear, and other mechanism.

The boat moved forward and back, turned right and left, described figures, was guided to definite points, rang bells, exhibited flags and lights, fired guns, etc., giving proof of effective control.

Long Distance Wireless.

In recent tests carried out in Washington, D. C., by Mr. L. W. Austin, for the purpose of determining the law of the variation of strength of signal with distance, he found that over salt water the electrical waves decrease in intensity in proportion to the distance, as found by Duddell and Taylor. In addition, they are subject to an absorption which varies with the wave-length. This is true in general for day transmission. The absorption at night is entirely irregular, varying from zero to the day value, but is on an average much less during the Winter than in Summer. Variations also appear to occur during the daytime, but these are probably in general small. The received antenna currents between two stations with salt water between are proportional to the product of the heights of the sending and receiving antennas and inversely proportional to the wave-length, provided the antenna resistances

Digitized by Google

remain constant. The experiments recorded were carried on with flat-top antenna heights of from thirty feet to eighty feet and wave-lengths of from approximately 1,500 meters to 4,000 meters.

An account of the test is published in the Bulletin of the Bureau of Standards.

The Telephone.

Mr. Fred. G. Greber, assistant chief engineer of the Southwestern Telegraph and Telephone Company, Dallas, Tex., has been promoted to be general manager of the West Texas Telephone Company with headquarters at Brownwood.

Mr. Henry W. Pope, secretary of the Telephone Pioneers of America, New York, met with a painful injury in a subway train recently. His hip was badly sprained and he has been confined to his house for the past three weeks in consequence.

Mr. Howard T. Reneau, for several years with Nelson Morris & Co., at St. Louis and New York, and more recently with the Postal Telegraph-Cable Co. at Albuquerque, N. M., is now in charge of the American Telephone & Telegraph Company's repeating station at Albuquerque.

National Independent Telephone Convention.—The next annual convention of the National Independent Telephone Association will be held in Chicago, February 7, 8 and 9, 1912.

"The Wonderland of the Telephone."—Mr. William A. Dockery, of the New York Telephone Company, lectured on December 21 on "The Wonderland of the Telephone" in an East Orange, N. J., church.

"How to Use the Telephone."—This is the title of a neat booklet issued by the Southern Bell Telephone and Telegraph Company to its employes. It would be of benefit if instructions of this character were issued more generally to the public.

Postal Telephone Rates in California.—The Postal Telegraph-Cable Company announces a rate of 25 cents for a ten-minute telephone conversation between San Francisco and Sacramento, Cal. This is a large reduction on the present rates.

Telephone Amalgamation in San Francisco.—Legal steps have been taken looking to the merging of the Home Telephone Company of San Francisco, Cal., to the Pacific Telephone and Telegraph Company. The Home company operates an automatic system.

Governmental Telephony in Manitoba.—The operation of the Manitoba Government telephone system for the year 1911 will show a loss of nearly $150,000. The commissioners will recommend radical changes bearing upon the matter of rates. There are 200,000 telephone users in Manitoba.

Bell Telephone Stations for 1911.—It is stated that the American Telephone and Telegraph Company will make a gain in stations during 1911 of over 600,000 compared with 740,027 in 1910. It was estimated that the company would have 6,500,000 stations on December 31, of which 4,500,000 are Bell stations proper and 2,000,000 stations of connecting companies.

Sunset Telephone Company Buys Opposition Plant.—The Sunset Telephone and Telegraph Company on December 9 purchased, at a Federal court auction, the Home Telephone Company, which operated an automatic telephone system in Tacoma and Bellingham, Wash. The Home Company went into the hands of a receiver a year and a half ago and later into bankruptcy. The price paid was $550,000.

Conference of Telephone Traffic Superintendents.—Division superintendents of traffic for the Southwestern Telegraph and Telephone Company from various points in the Southern states met in conference in Houston, Tex., December 7, 8 and 9. Among those present were: L. M. Loring, of Little Rock; J. J. Trapp, of Fort Worth; R. E. Hart, of Houston, and D. M. Parkinson, of San Antonio. W. B. Kellogg is division superintendent in Dallas.

The New York City Telephone Directory.—The new telephone directory of the New York Telephone Company contains 760 pages and 275,000 names. Five hundred thousand copies were distributed throughout the whole of New York City. The paper used in this book is very thin and strong and is especiallv made for the purpose. A new type has been designed for this work and will be used for the first time in the next issue of the directory. The present printing plant turns out 20,000 completed books a day, but its capacity will be enlarged to 40,000 copies a day, and even at this speed it will require two weeks to print a single edition of the book. Thirty-three years ago the New York City telephone directory was a card containing 252 names.

Independent Telephone Companies in New York State Absorbed by the Bell Interest.—The New York Telephone Company has obtained a substantial control of the bonds and stocks of the following independent telephone companies in New York State: Commercial Union Telephone Company, operating at Troy, Glens Falls, Saratoga, Lake George and other important points; Albany Home Telephone Company and its subsidiary company, the West Shore Home Telephone Company operating at Catskill; the Cohoes-Waterford Home Telephone Company operating at Cohoes and Waterford; the Rensselaer Home Telephone Company operating at Rensselaer; the Schenectady Home Telephone Company, Schenectady; the Citizens Standard Telephone Company operating at Kingston and vicinity; the Dutchess County Telephone Company, Poughkeepsie; and the Independent Union Telephone Company, the toll line system connecting these plants. The total number of telephones involved is approximately 25,000, and several hundred miles of toll line. The price paid is in the neighborhood of $3,000,000.

Telephone Pioneers of America.

FRANK B. COOK.

It is seldom that we find a man who possesses in any marked degree the inventive genius and also a faculty for business; but in the well-known inventor, Mr. Frank B. Cook, we have that rare combination in the electrical field of a prolific inventor and a successful business man, one who has made a financial success manufacturing his own inventions.

Like many other telephone men he started his electrical career in the telegraph field, beginning

F. B. COOK, OF CHICAGO, ILL.

in 1876 as a line constructor and fitting up and wiring telegraph offices. He began his telephone career in 1878, setting up and testing telephone lines for Mr. William Kline, superintendent of telegraph of the Lake Shore and Michigan Southern Railway Company at Toledo, Ohio. He settled down to regular telephone work on June 15, 1879, in the employ of the Toledo Telephone Exchange Company, Toledo, Ohio, which company was later absorbed by the Central Union (Bell) Telephone Company.

Starting as foreman of construction he successively filled various positions until he became chief engineer having charge of all equipment and apparatus as well as construction work in a territory comprising some two hundred exchanges and distributed over the States of Ohio, Indiana, Illinois and Iowa.

In September, 1896, Mr. Cook resigned his position with the Central Union Telephone Company and moved to Chicago to engage in the manufacture of telephone apparatus for independent telephone companies, the apparatus manufactured being almost entirely of Mr. Cook's personal patents; he having invented some hundreds of devices, apparatus and circuits, many of which resulted in patents. But while his inventions are many and varied they hold closely to telephone protective apparatus, his protectors being used throughout the world.

To Mr. Cook alone with his untiring and indomitable energy is due the success of the large business which he personally owns; for, he started without capital and, in addition, has carried on the work without the assistance of outside capital.

Early Days of the Telephone in Albany.

In the early part of 1877 the first telephone line in Albany, says Mr. W. B. Eddy, of that city, was strung from the office of the Atlantic and Pacific Telegraph Company to Mr. Charles Sewall's house in Bath on the Hudson. In 1878 the first toll call was passed from the office of the Atlantic and Pacific Telegraph Company to S. K. Rupley at Poughkeepsie. Early in the same year the American District Telegraph Company, which had been furnishing Albanians messenger service, procured Bell instruments, with a franchise giving it the right to operate in thirteen counties comprising most of what is now the Hudson District, and formed the first telephone company. It opened the first exchange at No. 470 Broadway.

The first "Opposition" was begun in 1879 by the Commercial Telephone Company which used the Edison instruments and was under the direction of the Western Union Telegraph Company. The Commercial people opened an exchange at No. 558 Broadway in the American Express Building and conducted such a lively campaign against the American District Telegraph & Telephone Company that in 1880 the two consolidated. This was the only case in the United States where an opposition or Edison company absorbed the Bell interests. The Commercial Company, with A. B. Uline as manager, removed four hundred duplicate telephones and established the main office at 470 Broadway with branches on Washington Avenue and on South Pearl Street. It sublet the Hudson territory to different independent companies and did business in Albany with indifferent success until 1883 when it was taken over by the Bell people and became a part of the Hudson River Telephone Company.

Mr. Vail and Old Farmer Lawton.—While Mr. Theo. N. Vail was in Denver, Col., recently, he was met by "Old Farmer Lawton," the well-known old timer, who is an old friend of Mr. Vail. On his departure from the city Mr. Vail presented Mr. Lawton with a copy of "The History of the Telephone," in which Mr. Vail wrote: "To old farmer Lawton, from another old farmer, Theo. N. Vail."

Mr. W. H. Stansell, manager of the Postal Telegraph-Cable Company at Wilmington, N. C., in remitting to cover his subscription for another year, writes: "I cannot afford to miss a single number. For years I have read TELEGRAPH AND TELEPHONE AGE from cover to cover with much interest and helpfulness. The course of instruction in the elements of technical telegraphy alone, is worth many times the price of the paper."

The Postal Automatic.

BY DONALD McNICOL, NEW YORK.

In the Wheatstone system of automatic telegraphy, messages are perforated in the Morse code on paper strip. This tape is then passed through a Wheatstone transmitter which is operated by means of an electric motor. The Wheatstone transmitter is practically a high speed polechanger operated mechanically instead of by means of a key circuit and Morse operator. The preparation of the transmitting tape is accomplished by means of three-key mallet punches which may be operated by any telegrapher after a little practice. If the Wheatstone transmitter is run at slow speed the signals may be read as easily as hand sending; as the Morse is plain and beautiful. The speed over the line may be run up to two hundred words per minute depending upon the action of repeaters in circuits, the K R limitations of the line and the rapidity with which the polar relay will work satisfactorily. At the receiving end the signals are copied on a moving strip of tape by a Wheatstone recorder similar in construction to our call circuit registers; but of course capable of infinitely greater speed and more accurate reproduction. The received tape is then passed to copyists who understand the Morse code and who copy the message on the regular telegraph form by means of typewriters. Messages received by wire at any office for relaying to points beyond may be copied as above stated or the received tape may be passed to a Morse operator who transmits by hand directly from the received tape. If the message is to be forwarded from the relay office by automatic, the received tape must be translated and typewritten and then the message repunched on transmitting Wheatstone tape and sent over the line at high speed.

The Postal automatic system is identical with the Wheatstone in so far as concerns the preparation of the transmitting tape and the transmission of the signals from sending end, but the reception of the high speed signals is accomplished in an entirely different manner. The Morse signals are received by an electro-magnetic punch, or reperforator, which, instead of marking the dots and dashes of the letters on the receiving tape with ink as in the Wheatstone system, perforates the characters in a continuously moving strip of paper tape so that the received tape resembles the transmitting tape inasmuch as the Morse signals appear thereon in a series of perforations. The improvement in this method as compared with Wheatstone recorder reception is that the received tape may be passed through a local reproducer and the messages copied by ear from an ordinary sounder. These reproducers are motor-driven and are under the control of the reproducing operator so that the speed of reproduction may be regulated to accord with the ability of the operator to copy. At his convenience the tape may be stopped, pulled back and run through again in order to confirm doubtful words, so that in practice the reproducing operator is copying from a sender over whom he has absolute control in the matter of speed and of repetition. Moreover, with this system messages received at relay offices for points beyond which are equipped with automatic apparatus, may be relayed automatically, simply by passing the received tape through an automatic transmitter similar to the reproducer. In this case the reproducer operates the regular duplex polechanger in the same way as it operates the sounder for local reproduction.

The accompanying diagram shows the wiring of the reperforator circuits. Information regarding the construction of and operation of Wheatstone sending tape perforators and transmitters applies equally to this system.

The operation of the receiving punch (or reperforator) is shown theoretically in the illustration. It will be observed that the main line polar relay instead of operating a reading sounder as is customary in ordinary duplex work, operates

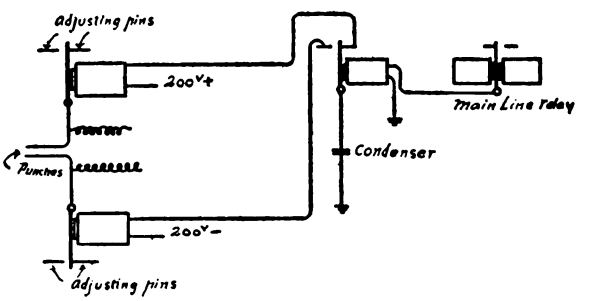

DIAGRAM OF AUTOMATIC PERFORATOR.

an extra polechanger the armature of which is grounded through a condenser. Two pair of magnets in the punch have circuits leading through their windings from a two-hundred-volt battery of each polarity. These magnets control the movements of two armatures which on their free ends are equipped with steel punches about ⅛ of an inch in diameter and one inch long which, when the magnets are energized, travel through holes in a die plate and perforate holes in a strip of tape which is being drawn through a slot and past the holes in the die plate. The tape is moved continuously by means of a tape transmission and take-up gear operated by an electric motor the speed of which is regulated by a rheostat. A closed key or marking current from the distant station closes the home polar relay which in turn closes the polechanger shown, thus permitting the condenser to discharge and momentarily energize one pair of magnets. This magnetization draws the armature toward the electro-magnet thus forcing a punch through the paper strip. As the distant key opens and a spacing current is sent to line the home main line polar relay opens, thus opening the extra polechanger local circuit which permits the retractile spring of the same to pull its armature into contact with the back stop thus allowing the opposite battery pole momentarily to

Digitized by Google

energize the other magnet of the punch, forcing the other steel punch through the moving band of paper tape. The resultant holes appearing in the tape form the Morse characters. The punches should be adjusted to travel forward just far enough to go through the paper and make a clean round hole, and backward just far enough to clear the face of the die plate. In view of the fact that the tape is continuously passing through a slot in front of the punches, the act of punching the holes must be accomplished by extremely rapid movement of the steel punches so that there will be no tendency to tear the tape. The speed at which these punches move forward and backward in response to the operation of the extra polechanger is regulated by having the capacity of the two 3 m. f. condensers just right and by adjusting the tension of the strong retractile spring attached to the armature lever of the punch so that when the punches are travelling the required distance to and fro, the action is very rapid and not "draggy."

It is evident that the tape being perforated is stopped each time that either the upper or lower punch is in the act of perforating a hole and as each punch is operated many times per second it is necessary so to adjust the tape-moving mechanism that these momentary stoppages are compensated for by "slip" in that part of the gear which pulls the tape through the slot.

The instruments have been designed to do this satisfactorily and it has been found that attendants can, with little practice, learn the correct adjustment. The present method of taking care of the received tape coming from the reperforator is the same as that used in caring for the original transmission tape as turned out by the Wheatstone perforator; that is, by rolling it up by hand as it comes from the receiver.

The receiver when in operation requires constant attention and it is quite convenient to take care of the received tape in the manner referred to. The received tape may be parceled out in units of one message, two messages or in any number required by traffic conditions, as the receiver attendant very quickly learns to read the tape and is able to follow the wording as perforated thereon. The end of each message is signified by a paragraph sign (----) or by a succession of letters (a) without spaces between them.

The code used is the Morse alphabet except that the letter L is changed from long dash (—) to one dot and three dashes (. ---). The received tape is passed to the reproducing operators in whatever size bundles the traffic demands and by them is run through local reproducing machines at a speed to suit the convenience of the operator. The operation of the reproducers is quite simple and may be learned by any operator in an hour or two.

Report of Old Timers' Reunion.

The printed volume of proceedings of the Atlantic City reunion of the Old Time Telegraphers' and Historical Association and the Society of the United States Military Telegraph Corps, September 5, 6 and 7, has been distributed among the members. It contains 120 pages including many illustrations and is printed on fine coated paper the work having been done by the James Kempster Printing Company, New York.

Considerable taste is displayed in the get-up of this volume, and it will form a very attractive addition to its predecessors. The design of the front cover is very neat, and on the back cover is an embossed reproduction of the badge used at the reunion which is artistically executed.

Among the many illustrations are several Atlantic City views, and one of the bronze tablet for the Turner monument, also the bronze tablet of the United States Military Telegraph Corps unveiled at Pittsburgh, Pa., April 1 last. The frontispiece consists of an excellent picture of Col. W. B. Wilson, president of the Old Time Telegraphers' and Historical Association and Society of the United States Military Telegraph Corps, Holmesburg, Philadelphia, Pa. Mr. David Homer Bates, the secretary of the Society of the U. S. Military Telegraph Corps, who has done so much active work in its behalf, is also represented among the many pictures.

The book was gotten up by Mr. F. J. Scherrer, secretary of the Old Time Telegraphers' and Historical Association and reflects great credit upon his taste and judgment.

Speed of a Telegraphic Cable Message.—Mr. J. Rymer-Jones, of the Silvertown Telegraph Works, London, England, has issued a pamphlet describing his method of calculating the speed of a telegraphic message received through a submarine cable, using either the syphon recorder or Morse signals in international, American or other alphabets. It is highly analytical in character and a valuable addition to the subject. The working value of a cable is estimated by the number of words which can be sent through it per minute, of such legibility that an ordinarily skilled operator can readily decipher them, and the specification, therefore, generally provides for a suitable weight of conductor and insulator to convey so many standard words of five, seven, or ten letters per minute.

The determination of the speed of cables therefore is of the highest importance, and this excellent pamphlet gives a great wealth of detail as to how this can best be done. The pamphlet contains various charts and diagrams explanatory of the text. The price of this pamphlet is $2.00 per copy. Copies may be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Mr. W. C. Hirchert, manager of the Erie Railway interests at Salamanca, N. Y., writes: "I certainly want to keep in touch with the good things like TELEGRAPH AND TELEPHONE AGE as long as I can afford it." Mr. Hirchert has been a subscriber to this paper for twenty-five years.

KERITE

INSULATED WIRES and CABLES

DEPENDABLE

Kerite Cables installed upward ot 35 years ago, and exposed to deteriorating influences, are giving perfect service to-day.

EFFICIENT

Kerite does not rely upon the rubber in its composition for insulating efficiency. Kerite itself is a compound having superior insulating qualities.

SERVICE

A half century of successful service has demonstrated that Kerite possesses the essential qualities of safety, reliability and economy to an exceptional degree.

Kerite Insulated Wire and Cable Co.

The Railroad.

Mr. A. R. Kendall, train dispatcher for the Boston & Maine Railroad at Concord, N. H., has resigned to go into the insurance business. He is succeeded by Mr. Frank L. Ward of the chief train dispatcher's office at Boston.

Mr. Charles McDonald, station agent for the Boston & Maine Railroad at Hudson, Mass., has accepted the position of chief train dispatcher and train master of a railroad in Porto Rico.

The Union Station at White River Junction, Vt., in which the Western Union Telegraph office was located, was recently destroyed by fire. This was one of the largest relay offices north of Boston. Mr. Morris Walsh is the manager of the office.

Violating the Nine-hour Law.—The Cleveland, Cincinnati, St. Louis & Chicago Railroad Company has been adjudged guilty of violating the law fixing the working hours of railroad telegraphers at nine hours out of twenty-four. United States Judge Hollister rendered a decision to this effect at Columbus, Ohio, on December 12.

No Wireless Tests on Pennsylvania Railroad.—Newspaper reports were recently published to the effect that the Pennsylvania Railroad Company had been making tests of a wireless telegraph system on its line between Harrisburg and Altoona. Mr. J. C. Johnson, superintendent of telegraph of this road, states that there is no truth in the reports, that no such tests have been made by his company.

Telephone Train Dispatching.—The Chesapeake & Ohio Railway, Mr. C. W. Bradley, superintendent of telegraph, which has had for some time more than 200 Gill selectors in service in telephone train dispatching has now ordered from the United States Electric Company of New York, fifty-two additional selectors for a farther extension of its circuits. The Central Vermont Railway, Mr. M. Magiff, superintendent of telegraph, also a user of Gill selectors, has recently received thirty-one additional selective station outfits from the United States Electric Company, with automatic sending keys for the dispatcher's station. Another repeat order for Gill selector equipment recently delivered was from the New Iberia & Northern Railroad, in extension of its circuits.

The Turner Monument Fund.

The bronze tablet for the Turner Monument, which is to be unveiled at Harriman (Turner), N. Y., next spring, has been placed on exhibition in the window of the Gorham Manufacturing Company's New York establishment at the corner of Fifth Avenue and Thirty-sixth Street. An opportunity for several weeks will thus be afforded for the inspection of this excellent piece of bronze work before it is affixed to the face of the monument. Subscriptions toward the fund created to defray the cost of the monument, etc., are still coming in through the efforts of committeeman Mr. David Homer Bates, and many railroad presidents are now subscribing ten dollars each.

The contributions received up to date toward the monument fund are as follows: Previously acknowledged, $1,726.99; J. E. Childs, New York, $10; W. C. Humstone, New York, $10; E. W. McKenna, Chicago, Ill., $10; W. F. Weitbrec, Denver, Col., $10; John J. Ghegan, New York, $10. Total, $1,776.99.

Close of Our Subscription Contest.

It is with great pleasure that we express our appreciation of the extraordinary efforts put forth by some of our agents in the subscription contest, and our only regret is that all of them could not win the prizes. The interest taken in the matter by every one concerned was considerable, and those who failed to win a prize have the satisfaction of knowing that they fought in a noble cause.

The contestants were kept posted each week as to their standing and according to the conditions the competition closed at 3 p. m., December 21, and checks were mailed to the winners of the prizes on the same afternoon. The successful contestants were:

First prize, $50. Won by Mr. B. I. Gable, of the Western Union Telegraph Company, Pittsburg, Pa., amount of subscriptions, $150; second prize, $25, Mr. E. C. Dodge, Western Union, Chicago, subscriptions, $126.13. As Mr. H. H. Dengler, of the Postal Company, Chicago, sent in business to the amount of $125.27, and was so close to Mr. Dodge's record, we decided to make his third prize equal in amount to that awarded to Mr. Dodge, viz.: $25. Fourth prize, $5, to Mr. W. W. Umsted, of the Western Union Company, Omaha, Neb., amount of business, $96.75; fifth prize, $5, to Mr. C. W. Alexander, Western Union company, Kansas City, Mo., amount of business, $48. As Mr. C. F. Bartlett, of the Postal company, St. Louis, Mo., sent in business to the amount of $47.80, we decided, on account of his being so close to Mr. Alexander's record, to award to him a sixth prize, $5.

Artificial Rubber.

Artificial rubber is said to have been produced from soja oil by two German chemists. This oil is prepared from the soja bean which is grown in China and has many valuable qualities. To obtain the artificial rubber, the oil is mixed with half its weight of nitric acid so as to give an emulsion, and this is heated to the boiling point of water. At the end of the heating there is produced a very uniform spongy mass. This is washed with water and then dissolved in five per cent ammonia, from which it is precipitated by a dilute acid. The precipitate is then washed, pressed and dried at fifty degrees centigrade. The result of these operations is an elastic substance resembling rubber and it is claimed that it can be vulcanized in the same way as natural rubber.

The Reid Monument.

The proposition to establish a fund for the erection of a monument over the grave of the late James D. Reid at Rochester, N. Y., is meeting with favor and matters are gradually assuming shape.

As announced in our issue for December 16 representatives of two telegraph societies have been named to appear for their respective organizations on the general committee which it is proposed to form for the purpose of carrying the work forward. Since that announcement another society has appointed delegates, viz.: the Postal Club of Atlanta, Ga., which will be represented by Messrs. G. H. Usher and W. C. Daviet.

The present stone on the grave is a plain flat slab, which lies horizontally. On it are engraved the words: "In Loving Memory of James Douglas Reid. Born in Edinburgh, Scotland, Mar. 22, 1819. Died in New York, April 28, 1901.

"He Giveth His Beloveth Sleep.
"Also in Memory of His Wife Nancy Elton Reid
Joined Her Husband Oct. 17, 1907.
"Life Is Eternal."

President C. P. Bruch of the Magnetic Club, New York, who originated the proposition, has invited the following telegraph organizations to co-operate in the movement to raise the necessary funds and erect a suitable memorial: Telegraphers' Mutual Benefit Association, Serial Building Loan and Savings Institution, Old Time Telegraphers and Historical Association, Society of the United States Military Telegraph Corps, New York Telegraphers' Aid Society, Gold and Stock Life Insurance Association, The Morse Club, New York, Association of Railway Telegraph Superintendents, Magnetic Club of Atlanta, Ga.

Representatives of the three societies so far appointed are: Society of the United States Military Telegraph Corps, D. H. Bates and C. A. Tinker; New York Telegraphers' Aid Society, T. M. Brennan and R. J. Marrin; Postal Club of Atlanta, G. H. Usher and W. C. Daviet.

When the remaining societies have appointed two of their members to represent them on the general committee a meeting of that body will be held to organize and arrange for the work.

U. S. Military Telegraph Pension Measure.

Mr. John Horn, retired, formerly of New York, and now a resident of Longueuil, Quebec, in a letter to Secretary David Homer Bates of the Society of the United States Military Telegraph Corps, on the subject of military telegrapher's pensions, writes:

"Referring to your campaign to secure pension rights for the survivors of the United States Military Telegraph Corps, so long unpatriotically delayed, as an old time telegrapher resident in the United States during the civil war, I know of their modest but heroic services; and the fact that some were Canadians whom I knew personally, including J. W. Pitfield of Nova Scotia, Frank Drummond of Quebec, Ed. Conway of Montreal, also A. J. Bosquet, and others long since deceased, makes me feel interested, and I sincerely hope that Congress at its present session will do full justice. That grand old man, of whom I never tire thinking, President Lincoln, spent much of the last four years of his life at the side of the telegraph operators in the War Department. Had he lived he would not have countenanced such gross injustice to these youthful telegraphers."

Mr. Bates states that telegraph operators all over the country will confer a great favor on their old military telegraph comrades by circulating petitions addressed to their congressmen asking for immediate favorable action on the Taylor bill now in the invalid pensions committee of the House of Representatives, as an act of long-delayed justice to the military telegraph operators, only about 200 of whom are now living, who served in the civil war. A considerable percentage of the membership of the corps were captured by the enemy and languished in confederate prisons for months, many of them dying there.

Operators who circulate these petitions are requested to have them signed by as many persons as possible and mail them direct to Congress before February 1. The bill is known as "Bill H. R. 2920. Granting pensions to military telegraphers."

President Col. William Bender Wilson, of the Society of the United States Military Telegraph Corps, suggests that every telegraph office throughout the country might be made a centre for the circulation of petitions to the Senate and House of Representatives to take favorable action on the Taylor measure, the petitions to be forwarded direct to Washington before February 1. The campaign to secure pension rights for the members of the United States Military Telegraph Corps is under the management of Mr. A. A. Zion, of Indianapolis, Ind., and is making great progress. It is nation wide, reaching to all influential sources, and the early reports coming in point to success.

North American Telegraph Co. Building New Lines. — The North American Telegraph Company is stringing eight additional wires on the new line of the Chicago division of the Milwaukee, St. Paul & Sault Ste. Marie Railroad, between St. Paul and Minneapolis.

Bound Volumes of the Age for 1911.—Orders for bound volumes of TELEGRAPH AND TELEPHONE AGE for 1911 will now be received. The price per volume will be $3.50, charges collect. This volume is of special value and interest to telegraph and telephone men as it contains a complete record of the important happenings in one of the most eventful years in the history of the telegraph and the telephone.

WHAT IS SERVICE ?

IT IS THE FURNISHING OF WHAT YOU WANT WHEN YOU WANT IT.

The New York Central needed 250 Selective Telephone Dispatching Outfits.

We made complete delivery of Gill Selector Outfits in two weeks' time.

Our understanding of Service does not end with the shipment of the equipment.

UNITED STATES ELECTRIC COMPANY
NEW YORK CHICAGO

New Book on Telephony.

A new book entitled "Modern American Telephony in All Its Branches," edited by Arthur Bessey Smith, is now ready for delivery. It contains over 800 pages and nearly 600 illustrations, and is the most complete and up-to-date work on the subject. The price is $2.00 per copy. Address TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

THE NIGHT LETTER TELEGRAM

HAS MADE

A GOOD WORD COUNTER

a practical necessity for every telegrapher. One of these devices is now as essential a part of his equipment as a typewriter. On account of the increased demand for the **HUDSON WORD REGISTER**, which is the only counter on the market suitable for this class of work, the manufacturers have been able to reduce the price from $5.00 to $3.00 each.

Mailed to any address upon receipt of price. Remit by express or post office money order to

Official Diagrams of the Postal Telegraph-Cable Company's Apparatus and Rules Governing the Construction and Repair of Lines

This volume contains 134 pages, including 105 full-page diagrams; size 7 x 4½ inches; price 50 cents.

Fourteen pages are devoted to rules governing the construction and repair of telegraph lines; and four to the subject of standard tools. Submarine cable splices, underground cable splices, single-wire joints and aerial cable splices are also fully treated. Under the general head of Rules for Wiring Offices and Cable Boxes, the subjects of the terminal office, intermediate offices, submarine and underground cables, aerial cables, call circuits and call boxes, leased wire offices, branch offices, miscellaneous, are fully given. Then come rules for the care of motors and generators, explanation of and rules for the care of the Callaud battery, rules for the care of the Leclanche battery and resistance coils, following which is the table of Size and Insulation of Wire Cable for interior use, and that of Wire Gauges.

The nominal price for so large, important and complete a work, embellished with so many first class plates, made especially for it, makes the book a valuable acquisition, indispensable to every telegraph and electrical student. The book contains diagrams of the Phantoplex system, the latest development in the telegraph art. All of the engravings are made from the official blue-prints of the Postal company, and are therefore absolutely correct, and have been produced under the direct supervision of John F. Skirrow, associate electrical engineer.

All orders should be addressed to

New Building in Toronto for Canadian Pacific Railway.

The accompanying illustration is of the new office building now being erected at the corner of King and Yonge streets in Toronto, Ont., by the Canadian Pacific Railway Company for the accommodation of the various departments.

The new building will be sixteen stories high and fireproof throughout with a skeleton of steel girders and columns re-inforced with concrete. On the corner there will be a double entrance so arranged that it will give a diagonal passage between the two streets. It is expected that the building will be ready for occupation in about a year.

The railway ticket office, the steamship ticket office, the commercial telegraph receiving office and the Dominion Express office will occupy most of the ground floor. The fourteenth and fifteenth floors will be occupied by the commercial telegraph department.

The receiving office of the latter department will be open to the public at all hours. The fourteenth floor will be occupied by the superintendent and staff, and by the bookkeeping department, the operating room occupying the whole of the fifteenth floor, which, when completed, will be fully up to date in every particular in matter of equipment, facilities, and comfort of the operating staff.

Following is a list of the telegraph staff:

Superintendent's office — William Marshall, superintendent; F. C. Roberston, inspector; E. A. Speer, superintendent of construction; P. G. Galbraith, chief clerk; A. J. Mason, accountant; C. W. Maltby, stenographer.

Local manager's office — H. A. Shambrook, local manager; G. A. C. Phillips, chief clerk; W. C. T. Dobson, cashier; G. Paton, accountant; W. A. Ezard, chief day delivery clerk; M. Hart, night delivery clerk.

The staff of clerks in the receiving and delivery department number some thirty-five in all and the messenger staff numbers from sixty-five to seventy-five.

Operating department—H. J. Lillie, chief operator; J. D. Smith, assistant chief operator; E. McSweeny, night chief; M. J. Bayley, wire chief; C. T. Barber, traffic chief; J. R. Christie, all-night chief; C. W. MacDonald and W. Smith, assistant night chiefs; J. Clandinan, loop chief.

In addition to these there are eighty-one regular operators and ten check clerks on the staff.

Direct wires are worked with Montreal, Winnipeg, New York, Chicago, Buffalo, Detroit, Cobalt, Porcupine and many other cities and towns. The company also maintains telegraph branches at Toronto on the floors of the Toronto Stock Exchange, the Standard and Dominion Mining Exchanges, and the Grain Exchanges, furnishing direct wires thereto.

Interesting Telephone Exhibit at Kansas City.

The Bell Telephone Company made an interesting exhibit at the National Business Show held at Kansas City, November 20 to 25. It faced the entrance to the hall and on entering it presented the effect of a stage setting. The scene depicted was one of hauling telephone poles out of the northern pineries during winter. The forest, as well as the figures shown, was life size and stood out in bold relief, and with concealed lights in the rear, made a very attractive scene. This display occupied a space fifty-three feet in width, twenty-five feet high and a depth of twelve feet, being elevated eight feet above the main floor.

The main floor space, in which a switchboard was located connecting the various business displays, also a number of desk telephones to which the public had free access, was enclosed by a fence of white enameled cross arms supported by insulators. The telephone poles used were also enameled and supported standard cable and copper wires.

Mr. Val B. Mintun, Kansas City manager of the Missouri and Kansas Telephone Company, under whose direction the display was arranged, received many favorable comments from the visitors who attended the exhibition.

Dispensing With the Repeating Sounder.

Mr. D. B. Grandy of the American Telephone and Telegraph Company, St. Louis, Mo., referring to the working of quadruplexes without the use of repeating sounders, states that "from the numerous articles on the subject, it might be inferred that working a quadruplex without a repeating sounder on the neutral side, by reversing the transmitter points, were something new. As a matter of fact it has been done frequently on circuits of moderate length.

"When I left Boston in 1880," he continues, "the Boston-New York quadruplex had been worked that way for several years."

The Relief Fund of the New York Telegraphers' Aid Society.

BY R. J. MARRIN, PRESIDENT.

The recent entertainment and reception of the New York Telegraphers' Aid Society, was a brilliant success and it was a pleasure to see such large numbers in attendance. This speaks volumes for the support the society is receiving from the rank and file; also from the officials of the two leading telegraph companies.

The expenses involved in such an undertaking is very large for one evening's performance. Notwithstanding the fact that the affair is conducted in behalf of charity, everything must be paid for in cash. This year the disbursements amounted to $686.42, but it is a satisfaction to know, that, when the curtain went up, the financial officers were able to meet all obligations from the receipts that had been received. In connection with the income we are pleased to mention that president Theo. N. Vail, of the Western Union Telegraph Company, and president C. H. Mackay, of the Postal Telegraph-Cable Company, make substantial contributions each year to the relief fund and their welcome donations are of great assistance. The society through its officers, besides expressing their gratitude in the customary manner, reserves two choice private boxes which are at the disposal of the contributors.

Volumes could be written of the aid that has been extended through the medium of the New York Telegraphers' Aid Society. The work is carried on so quietly, yet, systematically that little is heard of this feature outside of the executive committee meetings, when chairman Edwin F. Howell, makes full statements of all disbursements of the relief fund and the matter is then thoroughly discussed.

In glancing over the books for a period of less than two years, some significant items appear. The burial of two poor telegraphers, and paying in part of the funeral bill of two others, relieving the distress of one hundred and twenty-two persons, securing the services of clergymen for burial services; arranging and conducting funerals, physicians' and nurses' services, buying medicine and necessaries for the sick room, invalid chairs, paying premiums on life insurance policies, visiting the insane in institutions, assisting invalids with transportation, and performing many services with more than a monetary value, for instance visiting the sick and looking after the dead. The good that this society is doing is not generally realized, but from what has been just stated some idea may be had of the labor of love for their unfortunate fellow-operators which the officers of the society are called upon to perform.

T. M. B. A. Assessment.—Assessment 533 has been levied by the Telegraphers' Mutual Benefit Association to meet the claims arising from the deaths of G. H. Frech at Red Bank, N. J.; W. V. Connell at Mayhew, Miss.; Olive L. Wood at San Diego, Cal.; H. W. Gillespie at Winthrop, Mass. and J. J. Kennedy at New York.

LETTERS FROM OUR AGENTS.

NEW YORK WESTERN UNION.

A. E. Hynds has resigned his position with the Commercial News Department, and is now working the private wire for The Corn Products Refining Company, New York.

Herbert H. Akers, also formerly with the Commercial News Department, is now located at Nashville, Tenn.

PHILADELPHIA, POSTAL.

Mr. J. J. Whallen, manager of the New York office, was a recent visitor on business connected with the company. J. J. O'Neill, chief clerk to Mr. C. E. Bagley, district superintendent, has resigned to go with the Standard Underground Cable Company. Mr. Wm. V. Madden has been appointed to succeed Mr. O'Neill. Mr. James O'Neill,

Digitized by Google

night receiving clerk, has resigned to go with the government in the Postoffice department at Washington. A new office has been opened at sixty-first Street and Woodland Avenue, and is in charge of Mr. William Greene, formerly of this office. Mr. C. Troeller has been appointed manager of the Atlantic City, N. J., office, vice Mr. W. M. Phillips, resigned.

PHILADELPHIA WESTERN UNION.

John C. McCarthy, for many years service clerk in this office, died on December 15.

Mr. Horace A. Shinn has just rounded out his fortieth consecutive year in this office and is hearty and well. He has charge of the Philadelphia baseball park during the Summer months.

Mr. C. B. Wood has recovered from his illness which lasted four months, and is again back at the office looking well.

Quite a few of the operators have taken advantage of the slight falling off in business to avail themselves of the opportunity and have gone to Jacksonville, Atlanta and other Southern points.

PITTSBURG, WESTERN UNION:

Theodore E. Moreland, repeater chief in this office, and a veteran military telegrapher, who has undergone a painful operation to save his right arm, is convalescing and expects to resume his duties in the repeating department in a few days.

Wm. J. Gilson, aged 59 years, repeater chief in this office, died December 13. Mr. Gilson was in the company's employ in this city since 1872.

RENO, NEV., WESTERN UNION.

Ever since the Comstock days, when fortunes were made and lost almost daily, Reno, Nev., has been an important relay office for both overland and local circuits terminating at San Francisco. Little is known of Reno in a telegraph way, although it is telegraphically historic. At the time of the Fitzsimmons-Corbett pugilistic contest at Carson, Nev., in the early '90s, something like 680,000 words of press matter passed through the Western Union office at Reno during the twenty-four hours on the day of the fight. With the limited facilities at this early date this was quite a task. Almost as much press matter was successfully handled from the Reno office at the time of the Jeffries-Johnson contest in July, 1910.

Repeatered at the Reno office at the present day are found such circuits as the San Francisco-New York, San Francisco-Chicago, Wheatstone and Morse duplexes, San Francisco-Denver, San Francisco-Salt Lake printer, several leased circuits and wires penetrating the rich gold fields of Nevada.

The great telegraphic song hit,
"SEND ME A NIGHT LETTER, DEARIE."
Good, catchy music; beautiful title design magnificently printed in colors. Title contains night letter. Sung all over New York, 17c. by mail. All popular music sent by mail.
B. L. BRANNAN,
195 B'way, N. Y.

The office is ably handled by Mr. E. D. Edwards, chief operator, assisted by Messrs. E. P. Hearn, O. L. Holloway and W. C. McCormick. Mr. G. L. Morgan handles the commercial end, and the Western Union office is one of the attractions of the city's business section.

Mr. Edwards is an expert electrician and is liberal with his electrical knowledge, to the extent that he is willing to spend his leisure time in imparting to his employes the knowledge he has gained through years of study and experience with electricity and electrical apparatus. Mr. Edwards holds a weekly class in electricity for the benefit of his employes and, while they are at present only in the primary stages, they are making good progress.

A certificate of membership in the Telegrapher's Mutual Benefit Association, 195 Broadway, New York, affording protection for the family and dependents in the amounts of $500 or $1,000, which is at once available and cannot be diverted from its mission, should be held by every eligible person between the ages of 18 and 45 engaged in telegraph and telephone service, either commercial or railroad. If those not now members could realize and fully understand the stern necessity for beneficial help too often experienced by bereft families, would they not make earnest effort to secure such provision? Write for particulars.

AMERICAN TELEGRAPHY AND ENCYCLOPEDIA of the TELEGRAPH
By WILLIAM MAVER, Jr.
1912 Edition—695 Pages—644 Illustrations
Ready about January 15th. New matter contains full description with diagrams of the d'Humy and the Creed re-perforators; the Western Union and the Postal quadruplexes; the Jones phantoplex; induction preventing devices; the Buckingham-Barclay printer, etc.—**PRICE, $5.—POST-PAID.**

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

The New Telephone Jack Switchboard.

PART I.

What we may say concerning telephone jacks and the new type of Morse switchboard is intended particularly for the information of Morse operators, especially wire chiefs and those who may be called upon to handle such apparatus after the old springjack and strap-bar type of switchboard has been discarded and the new standard equipment introduced. Already several of our large offices have begun modernizing, and it will not be long before others will follow, hence it is well to look ahead.

Incidentally now is a good time for ambitious operators to place themselves in a state of preparedness for promotion by becoming more or less familiar with the new arrangement. If they do this they will start almost even with every one else, for even the wire chiefs will have to study the situation as something entirely new; not that it is harder, but because the change is radical. As there is considerable curiosity displayed on the part of many concerning the construction and operation of the new switchboard, we will give a brief description of it for their information.

In the first place, there are no wedges, pegs, discs or vertical brass bars in any part of the board. Instead, the face of the board is filled with telephone jacks mounted in porcelain panels, each of which, about 8 inches by 5¼ inches in dimensions, has a capacity for sixteen jacks. Ten of these panels placed side by side in one section provides 160 jacks. This does not mean that 160 wires can be placed in one section, since each wire must be equipped with several jacks in series, as will be shown later, in order to patch, test and cut in loops, and other apparatus. As the main wires are placed side by side in horizontal rows, it is evident that forty is about the limit for one section. The jacks used in series with the line jack are taken from the vertical row above the wire jack in different rows of similar panels.

The face of the board is made up, as a rule, in the following order, although for a smaller number of circuits and requirements it may be altered if so desired. The bottom row consists of ten panels, each containing sixteen jacks in four rows; above this panel a steel bar panel about three inches wide extends horizontally across the board. This bar constitutes the mounting for the Morse signal drop. Then come three or four more rows of jack panels like that on the bottom if that many are required. If not needed, one row may be filled with blank panels. On the top face of the frame the battery lamp panels are placed. Each panel 8 inches by 5¼ inches in dimensions, contains six Edison base sockets for holding the battery resistance lamps.

Normally there is not a cord in the board except those belonging to the test sets on the shelf. When a desk, loop, or other apparatus is cut in, it is done by means of detached cords of various lengths and construction, having plugs at each end. The advantage derived by using detached cords is that the method minimizes the number occupying space; the day man is not encumbered by the cords for night or idle apparatus, nor is the night man by the day connections.

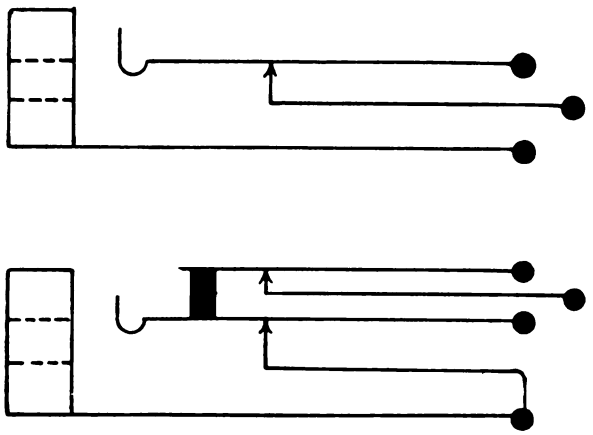
Telephone jacks are superior to springjacks in many ways; they are not so liable to become defective, for one thing, and they are particularly adapted for preventing mistakes. For instance, it will be impossible for any one to reverse the sending and the receiving sides of a loop, as often happens when a wedge is used. The plug can only go in one way and that is the right way.

Again, the telephone jack offers a ready means of avoiding delays due to the opening of the local circuits of multiplex apparatus when a grounded loop has been removed and the operator or attendant does not promptly turn the switches. By means of jacks, specially constructed, the cutting in or off of a duplex loop makes no difference whatsoever to anyone concerned, as dummy grounds are auto-

Digitized by Google

matically substituted for the loop removed by the operation of removal.

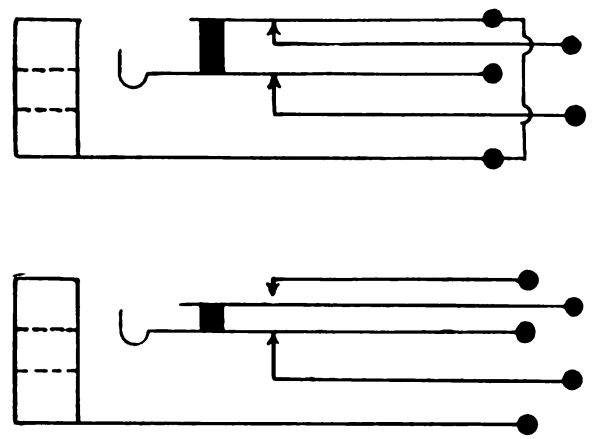
As previously stated, telephone jacks are not all constructed alike. A jack suitable for a linewire or a loop would not do for an office loop at all. Nor would either of the two mentioned be used for multiple trunk circuits. Then there is a fourth type used principally in concentration units which in like manner would not be available for any of the



FIGS. 1 AND 2.—TELEPHONE JACK SWITCHBOARD.

above circuits; hence it would be advisable to acquire an early knowledge of the construction and purpose of each type mentioned in the specification instruction papers.

The principal types used, and which will be sufficient to begin with, are: Type WE200A (Fig. 1). A two-conductor jack, with a circuit closing spring, when no plug is inserted, called the "normal con-



FIGS. 3 AND 4.—TELEPHONE JACK SWITCHBOARD.

tact." The jack has three terminal lugs. This jack will be used principally in main and loop switchboards for in- and out-circuits, such as a single wire, loop, desk, etc.

Type WE 201A (Fig. 2) is used principally in the concentrated unit system. Its purpose is to open the signal lamp circuit when the operator inserts the plug belonging to his Morse relay. It has four terminal lugs.

Type WE202A (Fig. 3) is used in connection with "office loops" for multiplex sets. It has four spring blades and four terminal lugs, two of which are each connected to a resistance unit of a value equal to that of a duplex loop, and which open or close simultaneously according to whether a loop is inserted in the jack or removed.

Type WE203A (Fig. 4) is used in multiple trunk circuits and also has four springs and four terminal lugs, but, as shown in the illustration, the springs are differently arranged.

There are a few other types used, but a study of these will show the importance of looking up the others when they are described.

In the next installment of this article we shall illustrate a number of circuits and groups of jacks that constitute the wiring and general make-up of the switchboard for practical operation.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. E. Reynolds, auditor, recently visited Philadelphia, Baltimore and Washington on company business.

Mr. D. H. Gage, Jr., of the electrical engineer's department, was in Philadelphia recently on company business.

Mr. F. W. Daly, manager of the office at 1775 Broadway, New York, has resigned and is succeeded by Mr. L. Schwartz, formerly manager at 441 Broadway.

Mr. W. A. Sterner, manager at Jamestown, N. Y., gave his messenger boys a dinner at his home on New Year's day. The boys appeared in brand-new uniforms, and after the dinner were entertained with a magic lantern.

Mr. P. J. Mackin, manager of the Springfield, Mass., office was a recent executive office visitor on company business. Mr. Mackin entertained his messenger boys at his home New Year's eve, with a collation and music, each of the boys contributing something either in vocal or instrumental lines.

Mr. F. J. McKenna has been appointed manager of the Postal Telegraph Cable Company at East Liberty, Pittsburgh, Pa., vice F. L. McGowan, resigned. Mr. McKenna was for a number of years assistant to the manager and inspector for the Western Union Telegraph Company at Pittsburgh. He is a man of exceptional ability and assumes his new position with a large experience.

Mr. T. P. Wheeler, a veteran St. Louis, Mo., telegrapher, who retired from the service of the Postal Telegraph-Cable Company eight months ago has so much improved in health that he has returned to the service in the St. Louis office.

John Heyer, aged 43 years, formerly an operator at 253 Broadway, and latterly employed in a broker's office, died in Brooklyn January 5.

This company has opened an office in the Vanderbilt Hotel, corner Thirty-third street and Fourth Avenue, New York. Miss M. A. Goodwin is in charge of the office.

Magnetic Club Election.—The annual meeting of the Magnetic Club was held at 253 Broadway, New York, January 11, and the present officers were re-elected, as follows: C. P. Bruch, president; M. R. Cockey, B. M. Downs, T. L. Cuyler, Jr., E. B. Pillsbury, first, second, third and fourth vice-presidents respectively; W. B. Dunn, secretary; J. J. Cardona, treasurer.

Mr. J. F. Skirrow was elected to the board of governors in place of Mr. Isaac Smith.

Past-presidents W. J. Dealy, E. H. Johnson and W. H. Baker were elected honorary members.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr. Theo. N. Vail, president of this company and of the American Telephone & Telegraph Company, was elected an honorary member of the Morse Club at the meeting of January 10.

As a result of the recent trip to Chicago of Mr. C. H. Murphy, general superintendent of time service, New York, certain changes and improvements have been made in the service in that city. Mr. F. W. Brainerd, formerly a district manager in Chicago, is now manager of the time service in the Western Division.

Mr. F. H. Lamb, special agent of this company at Los Angeles, Cal., has been transferred to San Francisco, where he will fill a like position. Mr. Lamb was formerly and for many years district superintendent at San Francisco.

H. N. Tannenbaum has been appointed assistant general purchasing agent of this company, with headquarters at New York.

Mr. R. O. Holton has been appointed manager of the Selma, Ala., office, vice R. L. Smith.

Mr. W. V. Duke, manager of the Evansville, Ind., office of this company, has been appointed special agent for the company. He has been in the employ of the Western Union Company for forty years.

Mr. B. M. Gosselin, quadruplex chief, Chicago, was a recent New York visitor on business connected with the service.

Every employe of this company received a letter signed by president Theo. N. Vail as a token of appreciation of the officers of the company of the efforts of the employes and extending the compliments of the holiday season.

Mr. W. R. Edmondson, recently appointed manager of the Jacksonville, Fla., office of this company has spent all his life in the South. He was born in Nashville, Tenn., January 9, 1883, and began his telegraphic career December 6, 1899, entering the service of the Louisville & Nashville Terminal Company in Nashville. He afterwards became district manager for the Western Union Company in the State of Mississippi, with headquarters at Jackson. The two companies named are the only ones he has held positions with.

Mr. Bailey H. Arter, whose appointment as manager of the Texarkana, Tex., Western Union office was announced in these columns December 16, 1911, was born in Cairo, Ill., April 8, 1886, and has been in the telegraph service since 1899. He has worked for both the Western Union and Postal companies at various places, also on western railroads. Mr. Arter has had considerable experience in fitting up offices and installing apparatus. He occupied a position in the Western Union St. Louis office when he received his latest appointment.

Morse Electric Club.—The annual meeting of the Morse Electric Club was held at 195 Broadway, New York, January 10, and the present officers were re-elected as follows: President, J. B. Van Every; vice-presidents, Belvidere Brooks and W. J. Dealy; secretary, Frank J. Scherrer; treasurer, R. J. Murphy; P. J. Casey and J. A. Hill, directors for three years. The regular dinner will be held at the Savoy Hotel, New York, on Saturday evening, February 17.

The Telephone.

Telephone Elections and Appointments.

Mr. Frank H. Bethell, of New York, has been elected vice-president of the New York Telephone Company and president of the Bell Telephone Company of Pennsylvania, the Delaware and Atlantic Telegraph and Telephone Company, the Diamond State Telephone Company, the Chesapeake and Potomac Telephone Company, and the Central District and Printing Telegraph Company, succeeding Mr. Union N. Bethell, who was appointed chairman of the Boards of Directors of these companies. Mr. F. H. Bethell is a vice-president of the Telephone Pioneers of America.

Mr. H. F. Thurber, vice-president of the New York Telephone Company, was elected vice-president of the same companies in the place of Mr. F. H. Bethell. Mr. Thurber resigned his position as general manager of the New York Telephone Company, which place has been filled by the promotion of Mr. J. A. Stewart, superintendent of plant. Mr. G. C. Allen succeeds Mr. Stewart as superintendent of plant.

Mr. M. H. Buehler, a telephone pioneer and for many years general manager of the Central District and Printing Telegraph Company, was appointed second vice-president and general manager of the Chesapeake and Potomac Telephone Company. His headquarters will be in Baltimore.

Mr. W. T. Gentry, president of the Southern Bell Telephone & Telegraph Company, Atlanta, Ga., was a recent New York visitor.

Mr. U. N. Bethell, president of the New York Telephone Company, New York, has the sympathy of his many friends in the telegraph and telephone fields in the death of his daughter, Marjorie, at Montclair, N. J., January 5. Miss Bethell was seventeen years of age.

Automatic Telephony in France.—The French Government has been testing an automatic telephone system at Lyons and, according to a Paris dispatch, all makers of automatic apparatus—national and foreign—will be invited to bid on the installation of an automatic service.

Automatic Telephone System Discontinued.—The use of the automatic telephone system by the Home Telephone Company exchanges in Tacoma and Bellingham, Wash., which company was recently purchased by the American Telephone and Telegraph Company, has been discontinued.

Examinations of Telephone Employes.—Examinations were held recently at the various district offices of the New England Telephone and Telegraph Company of the male employes of the commercial department on subjects pertaining to the conduct of the business. These examinations are held for the purpose of ascertaining the fitness and efficiency of the employes in dealing with the public.

New England Telephone and Telegraph Society.—At the meeting of the Boston Plant Chapter of the Telephone and Telegraph Society of New England, held January 9, the subject of discussion was "The Line Order Routine." Leaders in the discussion were Mr. F. R. Starkey, assistant division superintendent of plant, Boston and Southern Massachusetts divisions; Mr. Philip Harvey, special agent for the general superintendent of plant; Mr. George L. Call, district wire chief, Newton suburban district; Mr. Charles F. Barker, district foreman, Somerville suburban district.

Advertising by Telephone.—The distribution of advertising hand-bills having been prohibited in Paris enterprising canvassers are turning to the telephone to stimulate their trade. They call up some one and inform him or her that the best place in Paris to buy shoes, or whatever may be the article offered for sale, is so-and-so's establishment on such a street. The Parisians are greatly annoyed and disgusted.

Free Instruction in Telegraphy for Telephone Employes.—Any employe of the Bell Telephone Company of Pennsylvania and Associated Companies, who so desires, may receive free instruction in telegraphy at any of the Western Union Company's telegraph schools. These schools are now maintained at Philadelphia, Baltimore and Washington, and one in Pittsburgh is planned; but employes of the telephone company may obtain the same course of instruction by applying to any of the managers of the Western Union's independent offices.

Telephone Pioneers.

The following corresponding secretaries for the Telephone Pioneers of America have been appointed by Secretary H. W. Pope, New York: Mr. Wm. J. Maiden of the Chicago Telephone Company, Chicago, for the Central Group telephone companies; Mr. H. W. Ballard, Denver, Col., for the Mountain States Telephone Companies' territory, and Mr. Geo. W. Foster, Dallas, Tex., for the Southwestern Telephone Company territory.

Personal.

Among the honors conferred by King George of England on the occasion of his visit to India was that of M. V. O. (fourth class) upon Mr. Ivor C. Thomas, director of the Indian government telegraph department.

Mr. Donald Murray, of London, England, inventor of the Murray printing telegraph systems, was married in New York to Miss Patricia Cosgrave on January 5. Mr. Murray's many friends extend their heartiest congratulations. He is in the United States on business in connection with his inventions.

Telegraph and Telephone Stock Quotations.

Following are the closing quotations of telegraph and telephone stocks on the New York Stock Exchange January 10:

Reductions in Cable Rates.

Following is a copy of a circular issued by the Commercial Cable Company signed by Mr. Geo. G. Ward, vice-president and general manager, announcing an important reduction of the Atlantic cable rate.

"(1) On and after January 1, 1912, the company will transmit, subject to the conditions of acceptance, messages written in plain language at a reduction of fifty per cent. from the charges for an ordinary message.

"(2) The message must be written in French or in the language of the country of origin or in the language of the country of destination. The sender must declare which of these languages is used. The sender must write before the address, and pay the charge on one word, for the letters LCF, LCO or LCD according to his declaration. This is a European government stipulation.

"(3) The message must have an address and a text. A signature is optional with the sender but the company will not be able to make unpaid enquiries about the senders of unsigned messages.

"(4) The address may be a cable address. House and street numbers may be expressed in figures.

"(5) The text must be written entirely in plain language without figures, commercial marks, groups of letters, abbreviations or mutilations. Numbers, except in the address, must be written in words. Genuine words spelled according to established usage, with not more than fifteen letters, will be charged as single words.

"(6) Messages written in the manner prescribed will be counted and charged according to the international regulations.

"(7) The messages will not be subject to artificial delay in transmission or delivery. Their transmission will only be delayed until ranking messages have been despatched and not more than twenty-four hours.

"Until further notice, only messages for Great Britain and Ireland can be transmitted at the reduced rate but we hope to announce extensions to other countries shortly."

The following announcements were made on December 28, 1911, by the Commercial Cable and Postal Telegraph-Cable Companies and the German Atlantic Cable Company with reference to cable rates to France and Germany:

"On and after January 1, 1912 (subject to the conditions prescribed in a recent circular for messages to Great Britain and Ireland) messages written in plain language of the country of origin or of destination (English or French), without figures, commercial marks, groups of letters, abbreviations, mutilations or combinations will be accepted for transmission to France at one-half the ordinary charges.

"On and after January 1, 1912 (subject to the conditions prescribed in a recent circular for messages to Great Britain and Ireland) messages written in plain language of the country of origin or of destination or in French, without figures, commercial marks, groups of letters, abbreviations, mutilations or combinations will be accepted for transmission to Germany at one-half the ordinary charges."

Postmaster-General Samuel of England, on December 30, 1911, announced that in addition to the deferred cable services between the United States and Great Britain, recently introduced, other European countries have come into the agreement. Germany, France, including Algeria, and Portugal announced their assent to the deferred service system. Messages from the United States and Canada may be sent to these countries at one-half the present rates, subject to the priority in transmission of the fast full rate messages.

A large number of British Colonial points are included in this reduction. They include Sierra Leone, Southern Rhodesia, Aden in Arabia, Ascension Island, Bathurst in British Africa, British North Borneo, Ceylon, Cocos Island, Cyprus, East Africa, Uganda, Gold Coast, India, Burma, Labuan Island, Northern Nigeria, Southern Nigeria, Perim Island, St. Helena, Somaliland, South African Union, Straits Settlements, Malay States and Zanzibar.

The Cable.

Mr. B. H. Reynolds, superintendent of the Central & South American Telegraph Company, New York, has the sympathy of his many friends in the death of his mother.

Cable for Mexican Telegraph Company.—The steamer "Iona" arrived at New York recently with 28½ miles of cable of the intermediate type for the Mexican Telegraph Company. This cable was manufactured by the India Rubber, Gutta Percha and Telegraph Works, London, England, and is for use in repairs to cables of the Mexican company in the Atlantic ocean and Gulf of Mexico. The cable was transferred into the tanks of the company's steamer "Relay" at New York, and the "Relay" cleared for the Gulf of Mexico on January 4 to effect some cable repairs.

Milwaukee Messengers.—The messenger boys of the Western Union Telegraph Company at Milwaukee, Wis., are given free instruction in telegraphy by a competent teacher, and several of them have qualified for service. The boys are also prepared for duties in the book-keeping, checking and telephone departments. Mr. J. J. O'Keefe, assistant manager, states that several of the boys have bank accounts. Three of the night messengers of the Postal Company in Milwaukee attend school in the day time, and four of the Western Union boys are earning their way through school by working as messengers.

Every one engaged in telegraphy and telephony should be a constant reader of TELEGRAPH AND TELEPHONE AGE. It gives the latest news in both these fields. Subscribe now. Subscription price, $2.00 per year.

The Cable-Rate Situation.

The following statement on the cable-rate situation was given out on January 5 by Mr. Theo. N. Vail, president of the Western Union Telegraph Company:

"It is said that intercommunication is civilization. The sole object of the Western Union is to improve the efficiency of its service and develop new services for intercommunication to meet the ever-growing business and social requirements, and its business motto is: 'We believe that the future development of the wire system in the United States will afford facilities for the annihilation of both time and distance by the general use of electrical transmission for written or personal communication, and will afford electrical communication of every kind of intelligence from every one at every place to every one at every other place. It will be comprehensive, universal.'

"To maintain as nearly as possible this universal telegraph service the Western Union has over 1,700,000 miles of wire connecting 25,000 regular Western Union offices; several thousand other points are connected by telephone. One of the peculiar burdens of maintaining a universal system is that of the 25,000 Western Union offices, three-fourths have less than $25 per month gross and only 10% of them over $100 per month gross. Each of these offices is and must be kept open at the expense of the whole if such a system is to be maintained. The Western Union has also an operating control of eight transatlantic cables.

"The whole business of electrical transmission of intelligence has been built up on the one idea of expedition. Expedition has been the essence of 90% of the cable and telegraph business. Expedition in intercommunication is an ever-growing necessity, but is costly. Business is confined to a few hours of the day and has rush periods in those few hours. Expedition, therefore, results in idle facilities. Anything which would interfere with existing business would be destructive and of no permanent benefit to the public.

"All talk about 'telegraph or cable war' or 'cut rates' is absurd. Not a single old rate has been cut or old service disturbed, nor will they be so long as the revenue is needed for the legitimate purposes of the company. The day of destructive competition is past. Competition should be aggressive but constructive and must be along legitimate and profitable lines.

"Bankrupt utilities cannot give the public acceptable service. Every innovation as to rates or services has been made by the Western Union after thorough study and deliberation, the purpose being the introduction of new and popular forms of business upon the theory that nothing in the way of a deferred business would be acceptable at any price where expedition was desirable. The use of highly elaborated codes for cable messages makes the cost per word of the actual translated message cheaper per word than any possible charge that could be made for plain language messages. The code or cipher is a business necessity.

"To claim that any telegraph or cable company is not a deferred message company is begging the question. The great trunk lines of railroad might as well say: 'We are not a freight line; we are a limited express line.' In the railroad business the deferred, i. e., the freight business, generally pays the bills and makes the dividends. The civilized countries are spending millions for fast and still faster trains and steamers to shorten the time of transit of all kinds of intercommunication. Why not use the idle telegraph and cable facilities for all business which could not stand the rate for expedition, but which would stand a moderate charge for something better than mail service?

"Negotiations to these ends were commenced two years ago, in the spring of 1910. It was, then, in the spring of 1910, that all the present innovations in cable rates which have recently been promulgated were decided upon, to be put into effect as soon as negotiations were completed and conditions right. The public announcement of the results of these negotiations was made by the postmaster-general in the English House of Commons December 5, 1911, in the following language: 'I have been in correspondence with the Western Union Telegraph Company of the United States in connection with the leasing by that company of the cables of the Anglo-American Telegraph Company and of the Direct United States Company. I am glad to be able to announce that, in view of this fact, the three companies referred to, i. e., the Western Union, Anglo-American and Direct United States, have consented to accept press messages which are not of an urgent character and which may be postponed to the more urgent traffic, at one-half of the present rates. I am in communication with the Commercial Cable Company also on this question. The Western Union Company proposes also, of its own initiative, to establish at once for the use of the public a system of so-called night-letters and week-end letters between this country and places in Canada and the United States.'

"It is not the purpose of the Western Union to rest content with what has been done. The night and day telegraph letters, and the deferred half-rate cable message, daily and week-end cable messages, are but the beginning of new services which will be within popular reach, and which will revolutionize business and social intercommunication."

The Deadly Hat-Pin.—A young woman operator in a Western town stuck her own hat-pin in her own eye while adjusting her hat. Women operators should have better sense. Hat-pins are made to injure other people with and not for performing surgical operations.

Appointments in Canadian Pacific Telegraph Service. — The following appointments in the Canadian Pacific Railway Company's telegraph service have been officially announced: Mr. W. J. Camp, electrical engineer, to be assistant manager of telegraphs with headquarters at Montreal; Mr. F. J. Mahon, superintendent at St. Johns, N. B., as superintendent of the eastern division with headquarters at Montreal; Mr. J. Fletcher, superintendent at Vancouver, B. C., as superintendent of traffic with headquarters at Montreal; Mr. D. H. Bowen to be assistant superintendent of the Ontario division; Mr. John Tait to be assistant to the general superintendent with headquarters at Winnipeg; Mr. John McMillan, superintendent at Calgary, to be superintendent on the Manitoba division with headquarters at Winnipeg; Mr. R. N. Young to be superintendent on the Saskatchewan division with headquarters at Moose Jaw; Mr. Donald Coons to be superintendent on the Alberta division with headquarters at Calgary; Mr. J. F. Richardson of Montreal to be superintendent of the British Columbia division with headquarters at Vancouver. Mr. S. J. Baker has been appointed acting inspector of telegraphs, Saskatchewan division with headquarters at Saskatoon.

Mr. John A. Wisely, chief operator at Halifax, N. S., for the Canadian Pacific Railway Telegraphs, has been appointed manager of the office, vice Mr. W. M. Godsoe, promoted to be district superintendent. Mr. Herbert Godsoe, night chief, has been promoted to be chief operator, vice J. A. Wisely, and Frank Bowes succeeds Mr. Godsoe as night chief.

Obituary.

G. M. Huntington, aged 79, an old-time and military telegrapher, died in New York December 28. In our issue for December 16, 1911, we published a letter from Mr. Huntington in which he gave an account of his experiences on the Erie Railroad and some interesting reminiscences of Charles Minot, general superintendent of that road, who sent the first telegraphic train order.

The Late Mrs. Kate P. Bruch.

In our issue for January 1 we published a brief notice of the death of Mrs. Kate P. Bruch, widow of Captain Samuel Bruch and mother of Mr. Charles P. Bruch, third vice-president of the Postal Telegraph-Cable Company, New York. Her death brings back to memory many past events. Her husband, Captain Samuel Bruch, was one of the most distinguished officials of the United States Military Telegraph Corps during the Civil War. At the outbreak of the war he was working in the Louisville, Ky., telegraph office, and during the summer of 1861 acted as censor for the Government over all telegrams for the South. Mr. Bruch afterwards became assistant to Anson Stager, manager of military telegraph in General McClellan's department, and at the same time was made general manager of the Southwestern Telegraph Company. In August, 1862, he was commissioned by the United States Government as captain and assistant quartermaster.

Captain Bruch died in Memphis, Tenn., March 31, 1865, and a monument was erected to his memory in the cemetery at Canton, Ohio, in which town he was born in 1831. This memorial was provided by the officers and employes of the United States Military Telegraph Corps, Military Division of the Mississippi.

Mrs. Bruch died at Clinton, N. J., the early home of her parents, where she had many friends, and was buried in her former home town, Canton, Ohio, beside the remains of her husband. At both the Clinton, N. J., and Canton, Ohio, services there were distinguished gatherings, including several prominent telegraph officials. Mrs. Thomas A. Edison attended the funeral services at Clinton.

Mrs. Bruch's lovable character won her many friends all through life, and she enjoyed the highest esteem in the various communities in which she had lived. She had an active mind and was prominent in church affairs.

Radio-Telegraphy.

High Speed Wireless Telegraphy.—Experiments with high-speed telegraphy on the Poulsen system have taken place between the Cullercoats station, near Newcastle-on-Tyne, England, and a Danish steamer at a distance of 496 miles. It is said to have been found possible to transmit up to 200 words per minute.

Wireless Station on Block Island.—The Massie Wireless Telegraph Company has erected a station on Block Island, R. I., in order to furnish a medium of communication with New Shoreham, cable communication with the main land having been interrupted. Messages will be sent to the Point Judith station, and thence distributed by telephone and telegraph.

London Radio-Telegraphic Conference.

We are informed by Major W. A. J. O'Meara, engineer-in-chief of the General Post Office, London, England, that the programme for the radio-telegraphic conference which is to be held in London June 4 has not yet been prepared. It will not be ready for a month or two yet, he states.

This conference will probably be the most important ever held in connection with radio-telegraphy, as many matters of international interest and of a pressing nature will be presented for consideration. All the civilized nations will be represented and several delegates from the United States will be in attendance, representing the various government departments concerned in wireless telegraphy. Since the United States is not a contracting party to the Berlin treaty, the representatives from this country will not be able to take direct part in the proceedings.

It is more than likely that the action of the London conference will be ratified by the United States, as the atmosphere in this country in wireless telegraphy is much clearer now than formerly, and the opposition to the ratification legislation will probably not be of a serious nature.

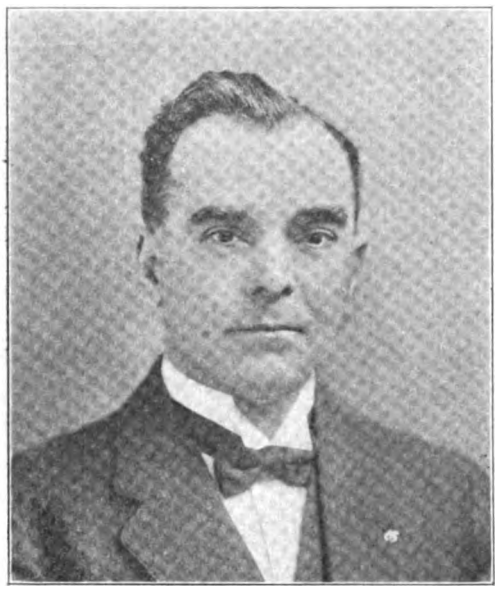
Telephone Pioneers of America.

P. K. HIGGINS.

One of the most "long distance" members of the Telephone Pioneers of America who attended the recent Boston convention was Mr. Pedro Kerr Higgins, who came all the way from Oklahoma to take part in the proceedings of the first meeting which took place at Boston, November 2, 1911.

Mr. Higgins, who is assistant to the president of the Pioneer Telephone & Telegraph Company of Oklahoma, has had a very extensive experience in the telephone business. He was born in Glasgow, Scotland, and entered the telephone service in that city in 1881. He filled the positions of night operator, inspector and chief test clerk for Scotland for the National Telephone Company in



P. KERR HIGGINS,
Assistant to President Pioneer Telephone and Telegraph Co., Oklahoma (1881).

Glasgow, and afterwards went to Chili, South America, as electrical engineer for the West Coast and The Chili Telephone Company. His technical education was received under such noted instructors as Sir William Thomson (Lord Kelvin), Henry Drummond and Andrew Jamieson, all of Scotland. Later he came to the United States and accepted a position with the Central Union Telephone Company as cable expert at Chicago, and afterwards as chief inspector at Indianapolis, Ind.

Mr. Higgins next went to Los Angeles, Cal., as superintendent of equipment for the Home Telephone Company, and afterwards accepted the position of general manager of the United States Long Distance Company in California. During his connection with the Pioneer Telephone & Telegraph Company of Oklahoma Mr. Higgins has filled the positions of superintendent of construction, general traffic superintendent and general superintendent, being at the present time assistant to the president.

Mr. Higgins made many friends in the East during his visit in connection with the Boston convention.

Rural Telephones in England.

It is no new thing that the isolation of many English country homes is a source of danger to them, says the London *Standard*. There are thousands of charming mansions, abounding in historical interest and housing valuable libraries and works of art, hidden away in extensive parks without any means of rapid communication with the outer world.

The telephone, in spite of its progress within the towns, is still unknown to them; and this although every year instances occur of the destruction by fire of one of them, through the lack of this safeguard. To resort to messengers on foot, horseback, or even motor car in the event of fire or robbery is not only courting disaster through delay, but means a reduction in the staff of persons available for home duty. Yet there are many who persist in taking all the old-time risks. The development of the telephone in rural districts is hopelessly behind that in the towns.

Much of this reluctance to adopt an undoubted boon and safeguard is due to ignorance. The facilities afforded by the telephone, apart from those of ordinary conversation with friends at a distance, are not generally known; neither have many people the slightest idea of the cost of installation. While it is unreasonable to expect instant and extraordinary developments from the transfer of the National Telephone Company's system to the Post Office on January 1, there is little doubt that some efforts will be made to popularize the use of the telephone in rural districts. The offer to farmers made early in the autumn by the Postmaster-General, although belated in comparison with similar developments in the United States, was but a prelude to further progress.

Damage to Underground Cables by White Ants.—Wide-spread depredations effected by white ants (termites) to state telephone cables are reported from Adelaide, Australia. The occurrence of crosses between the circuits in a lead-sheathed cable, drawn into earthenware ducts, led to the withdrawal of the cable, when it was found that the sheathing had been partly eaten away in places for several inches, nearly the full thickness of the lead, and in many parts the ants had eaten right through the metal. In Sydney, some time ago, it was reported that electric light cables were being attacked by the ants, and that, where the city tramway cables were laid on the solid system, the white ants got through the bitumen compound, and then attacked the lead sheathing, finally eating into the insulation of the high-tension cables, and breakdowns were caused as a result. The authorities decided that it was necessary to provide poison for the termites, and the bitumen in which the cables were laid was loaded with half an ounce of arsenious oxide per cubic foot of bitumen.

An Interesting Document of Professor Morse.

The insight possessed by Professor S. F. B. Morse in the early days of the telegraph as to the possible uses of his invention was truly remarkable, and it seems all the more so when we consider that his predictions and plans were announced so early in the history of the telegraph—practically concurrently with its birth.

Mr. Edward Lind Morse, of Stockbridge, Mass., son of Professor Morse, has furnished us with a copy of a manuscript, written by his father, without date, showing that Professor Morse foresaw the applicability of the telegraph to military and railroad purposes. The article is as follows:

"On September 10, 1838, a telegraph instrument constructed in the United States on the same principles, but slightly modified to make it portable, was exhibited to the Academy of Sciences in Paris, and explained by M. Arago at the session of that date. An account of this exhibition is recorded in the *Compte Rendus*.

"A week or two after I exhibited at my lodgings, in connection with this instrument, my railroad telegraph, an application of signals by sound, for which I took out letters patent in Paris, and, at the same time, I communicated to the Minister of War, General Bernard, my plans for a military telegraph with which he was much pleased. I dined with him by invitation, and in the evening, repairing with him to his billiard room, while the rest of the guests were amusing themselves with the game, I gave him a general description of my plan. He listened with deep attention while I advocated its use on the battlefield, and gave him my reasons for believing that the army first using the facilities of the electric telegraph for military purposes would be sure of victory. He replied to me, after my answering many of his questions:

"'Be reticent,' said he, 'on this subject for the present. I will send an officer of high rank to see and converse with you on the matter tomorrow.'

"The next day I was visited by an old Marshal of France, whose name has escaped my memory. Conversing by an interpreter, the Rev. E. N. Kirk of Boston, I found it difficult to make the Marshal understand its practicability or its importance. The dominant idea in the Marshal's mind, which he opposed to the project, was that it involved an increase of the material of the army, for I proposed the addition of two or more light wagons, each containing in a small box the telegraph instruments and a reel of fine insulated wire to be kept in readiness at the headquarters on the field. I proposed that, when required, the wagons with the corps of operators, two or three persons, at a rapid rate should reel off the wire to the right, the centre and the left of the army, as near to these parts of the army as practicable or convenient, and thus instantaneous notice of the condition of the whole army, and of the enemy's movements, would be given at headquarters.

"To all this explanation of my plan was opposed the constant objection that it involved the increase of the material of the army. The Hon. Marshal seemed to consider that the great object to be gained by an improvement was a decrease of this material; an example of this economy which he illustrated by the case of the substitution of the leather drinking cup for the tin cup hung to the soldier's knapsack, an improvement which enabled the soldier to put his cup into his vest pocket. For this improvement, if I remember right, he said the inventor, who was a common soldier, received at the hands of the Emperor Napoleon I the cross of the Legion of Honor.

"So set was the good Marshal in his repugnance to any increase to the material of the army that, after a few moments' thought, I rebutted his position by putting to him the following case:

"'M. Marshal,' I said, 'you are investing a fortress, on the capture of which depends the success of your campaign; you have 10,000 men; on making your calculations of the chances of taking it by assault, you find that with the addition of 5,000 more troops you could accomplish its capture. You have it in your power, by a simple order, to obtain from the government these 5,000 men. In this case what would you do?'

"He replied without hesitation: 'I should order the 5,000 of course.'

"'But,' I rejoined, 'the material of the army would be greatly increased by such an order.'

"He comprehended the case, and, laughing heartily, abandoned the objection, but took refuge in the general skepticism of that day on the practicability of an electric telegraph. He did not believe it could ever be put in practice. This was an argument I could not then repel. Time alone could vindicate my opinion, and time has shown both its practicability and its utility."

Automatic Telephony.—The number of localities now served by automatic telephones in the United States is 131; of these 30 have fewer than 100 stations, 94 more than 100 and six have the following numbers: San Francisco, Cal., 16,500; Los Angeles and Oakland, Cal., 24,000 and 8,000, respectively; Grand Rapids, Mich., 11,000; Columbus, Ohio, 14,000, and Portland, Ore., 12,000. An automatic system at Chicago is under construction. On the Continent of Europe the automatic system is in use in the following cities: Hildesheim, Altenburg and Munich, in Germany, and at Graz and Cracow, in Austria. At Amsterdam, Holland, a semi-automatic system is in course of installation. At Munich the Bavarian postal authorities intend gradually to transform the existing manual offices, so that in a few years' time the automatic system alone will be used to serve the 20,000 or 30,000 stations. In Austria it is intended to substitute the semi-automatic system for the manual in the central offices at Vienna. In England the system is being tentatively tried by the Post Office.

Reminiscences of Professor Morse.

BY HENRY A. REED, NEW YORK.

My first experience in telegraphy was in the Summer of 1849 at the village of Carmel, about sixty miles north of New York City and thirty miles southeast of Poughkeepsie. There were very few messages from or to Carmel. The office was opened and maintained mainly as a repair station, and the operator looked after trouble between White Plains, twenty-six miles north of New York City and Stormville, sixteen miles south of Poughkeepsie. Troubles were not infrequent. The line was built of two small copper wires, which, being soft, stretched in hot weather like molasses candy, and, being drawn up in Summer, they snapped as would the candy when contracted by the Winter's cold.

Quite small poles sufficed for the light copper wire, but when it was replaced by No. 9 iron wire the extra weight gave much trouble. Most of the lines at that time resembled more the single private telephone lines in our country districts than the substantial structures now in use.

In order to cover the southern section the Carmel operator had to drive six miles to Croton Falls and there take a train, watching from the back platform for the trouble. If it was discovered he got off at the next station and, with his repair outfit, footed it back, sometimes three or four miles.

As the drive of six miles made it difficult to catch trains, which were few and far between, the company decided to move the office from Carmel to the railroad station at Croton Falls. I made that change and in March, 1850, I opened at Croton Falls the first telegraph office on the Harlem Railroad. Few people at that time had an idea of the use of the new invention. The first day after the Croton Falls office was opened a lady arrived from New York without her trunk. The station agent got a description of the trunk and promised to send a letter down by the next train and get the trunk the next day. The telegraph was at his service free, but he did not think of it. However, I telegraphed a description of the trunk to the baggage master at White and Center Streets, New York, and it came up that evening.

After getting the Croton Falls office working I left it in charge of Mr. Stephen Lawrence who had learned the art from me, and on July 1, 1850, I went to Hudson, N. Y., which place I reached by Hudson River Railroad to Poughkeepsie and thence by day boat. The trains at that time did not run above Poughkeepsie, and the following Winter, 1850-1, the northern and western mails were carried from Poughkeepsie to Albany on the old style mail coaches, guarded by United States soldiers.

The following Summer, 1851, I saw the first train on the Hudson River Railroad pass Hudson on its way to Albany. In the Summer of 1851 I opened an office at Red Hook, twenty miles south, and at Valatie, fifteen miles north. At that time all offices between Croton Falls and Troy were on the post road. There were no lines on the Harlem above Croton Falls and none on the Hudson River road.

In the Summer of 1852 I left Hudson and came to New York as first assistant to Sam McGown, who soon after went to Australia and had charge of the telegraph and postal service of that country.

The New York, Albany & Buffalo Telegraph office was in the basement of No. 2½ Wall Street, New York, and occupied a room about 15 feet wide and 50 feet deep. The operators, three in number, occupied with their three registers the front window (the only window) and a space about 12 x 10 feet. Next, back, was the bookkeeper, Charles T. Chester, who soon after engaged in making electrical instruments. His section was about 12 x 5 feet. Next back of him were about six messenger boys occupying the same space, next a store room about 12 x 10 feet, and behind that a battery room with about 160 cells of Grove batteries with fumes that ought to have killed the whole lot. These details of New York's first office your readers may compare with the present equipments.

It was in this office in the fall of 1852 that I first met Professor Morse, a tall slim gentleman, sixty-one years old, with clean face, rather sharp but pleasant features and a very sweet smile. He handed me a message decorated with a skull in place of "D. H." directed to his wife in Poughkeepsie, and he waited until it was sent and "O. K." received.

New York did not agree with me. My nervous temperament needed more and better air than was to be had in that cramped office filled with acid fumes. In March, 1853, I was sent to the Poughkeepsie office, which was just a desk in the front part of the Wells, Butterfield & Co.'s express office.

Professor Morse's home, Locust Grove, was about two miles south of the village. There had been a line from Fishkill to Poughkeepsie with an office in the Morse homestead, with Augustus G. Davis, a cousin of Mrs. Morse, as operator, but the line had been abandoned and Davis had charge of the Poughkeepsie office for some time till he took Greeley's advice and went West to richer pastures, and later to Baltimore, where I think he is still engaged in the electrical manufacturing business.

The financial world was slow to appreciate the telegraph, but after a few lines were established and its usefulness was apparent, there was a great demand for lines and capital was so interested that Morse's rights seemed sure to yield fortunes. With this prospect he purchased about 300 acres on the road south of Poughkeepsie, extending from that road to the Hudson River, overlooking the river valley and the extensive vineyards and fruit lands of Milton and Marlborough on the western side.

He built a handsome residence on the southern

Digitized by Google

portion of the farm on the brink of the plateau some distance from the road, his entrance being through a large grove of very old locust trees. His western view was very extensive both up and down the river.

Professor Morse's visions of fortune were very soon obscured by clouds of infringement and his purse depleted by suits necessary to protect his patents. Under the strain he sold about two-thirds of his land, but was able to retain about 100 acres with his homestead until the clouds were cleared away, and to enjoy with his family and friends many years there of peace and plenty.

It is for abler hands than mine to write a history of Professor Morse and to show how a superior intelligence, untiring industry and indomitable energy inherited from an exceptional ancestry, together with a liberal education obtained by struggle, enabled him to attain a high place in art and science, and to be the first to invent a practical system of telegraphy. I will therefore confine myself to some personal experiences in my nearly twenty years of most friendly relations with him.

In looking over some letters from Professor Morse, I find one dated Thursday, November 30, 1854, from which we learn that in 1854 Thanksgiving was the last day of November, as it was in 1911.

The letter referred to was accompanied by a message to Amos Kendall, then in New York, asking Kendall to remain in New York until his (Morse's) arrival the next day, and as Thanksgiving day, being a holiday, and most telegraph offices were closed, he requested me to have that and other messages delivered as early Friday morning as possible. I was able to get them off Thursday afternoon.

In 1856 Professor Morse presented me with what I think was the first galvanometer used in this country for testing for faults, and it is now in the Smithsonian Institute at Washington, with other mementoes of early telegraphy.

For several years I had studied troubles and had in many instances been able to determine not only their nature, but very nearly the distance from my office. One day in the Summer of 1856 after completing my tests and giving directions to my repair man, telling him to get his kit and drive over the line south and that he would find a cross about ten miles from the office, I turned around and found Professor Morse standing behind me. He said: "What were you doing, Mr. Reed?" I told him that I was locating a cross. He had never heard of such a performance and was much interested in my explanation. The next day he brought me the little galvanometer which he had very recently brought from England, saying: "I think this will beat your fingers in measuring current." He was right and I never after used the finger and tongue method.

Professor Morse was very simple and democratic in his taste, but could play his part pretty well when in royal company. His portrait with his breast full of decorations was taken in Paris. On his return home he gave me a copy, saying: "What do you think of that, Mr. Reed?" I replied that I thought it very gay. "Well," he replied, "I do not enjoy such show and felt like a monkey when sitting for it, but you have to do such things on the other side."

Just after the civil war he took his family to Europe for a long stay and engaged a very successful teacher of Poughkeepsie as tutor to his children. I was in the stationery business at that time and had cards engraved for the tutor, John R. Leslie. Professor Morse happened into the store when Leslie called for his cards, and being shown one said to Leslie, who had just returned from the army: "What was your position in the army?" When Leslie replied, "Colonel," the professor said: "Mr. Reed, make a new plate, 'Col. John R. Leslie'; with that I can introduce him into the best society, but a plain name or 'Mr.' don't count over there."

When fortune first smiled on him he instituted a style of living in keeping with his position and prospects, including livery for his coachman. A few years later when war prices ruled and most people had to economize, we were speaking on the subject and the professor remarked: "Well, I sometimes think that one of my greatest mistakes was putting brass buttons on my coachman." Of course it was not the buttons alone, but the accessories which seemed burdensome for a while, but, with all his friends, I was much pleased that circumstances soon changed so that he was well able to continue the style to which his position entitled him.

In religion Professor Morse was a strong Presbyterian and his controversy with + John Archbishop Hughes on Roman catholicism showed him well versed in theology, but he was not accustomed to talk in meeting. Although a charming conversationalist he was not an after-dinner speaker unless he had time for preparation, and usually read from manuscript. In politics he was what was called a "Hunker Democrat," and when the civil war came on was considered a southern sympathizer. He did not wish for secession, but hoped for a compromise which would either retain slavery or pay for the slaves freed. He had many friends and some financial interests in the south and never favored what seemed to him abolition vagaries.

During the war he was much distressed by the heavy loss of life in Grant's campaigns and favored McClellan's tactics. He once said to me: "In war it is not so much the number killed as in position gained. It is like a game of chess, and now McClellan seems to have Lee checkmated." My reply was: "The trouble is that Lee don't seem to appreciate his position."

Professor Morse was very charitable, but methodical in his charities. A Hebrew tailor in Poughkeepsie was burned out and applied to Professor Morse for money to start again. The professor

Digitized by Google

furnished him the amount asked for but took his note payable in installments.

In 1864 my business partner, getting the get-rich-quick fever, got swamped in Wall Street, and in order to save the business I had to buy his interest in the book store and did not have the funds. I could have obtained help from others, but Professor Morse volunteered to loan me the $3,000 required, accepting my note at 6%, interest payable quarterly, the principal to be paid in four years or in installments as convenient to me. I was able to cancel the note in two years, and I still keep it with the several personal endorsements in grateful remembrance.

In 1866 I gave up telegraphy and the office was removed from my store, but as long as Professor Morse lived he had a drawer in my store where the Poughkeepsie merchants sent packages for Locust Grove and the Morse carriage stopped for the contents of the drawer whenever in town.

My wife has now in an old herbarium a pressed rosebud presented to her by Professor Morse and a small bouquet presented by Mrs. Morse a few days after our marriage in 1859.

P. Kearney and the Collins Overland Line

Mr. Phil Patsy Kearney, a well-known old-time telegrapher, now engaged in the mineral industry at Crown King, Arizona, has had an interesting career. He was born in Ireland in 1847 and entered the telegraph service in this country in 1865, at Erie, Pa., where he was employed by General Anson Stager, general manager of the Western Union Telegraph Company, with headquarters at Cleveland, Ohio. He was one of the party sent out by the Western Union to Siberia on the enterprise known as the "Collins Overland Line," to connect America and Europe. The other members of the party who signed at the same time, and assembled at New York City were William Kelsey, Joseph Pierce, and John I. Sabin, and they left New York for San Francisco on the Pacific Mail Company's steamship "Costa Rica," via Panama.

"On arrival at San Francisco," Mr. Kearney says, "we went aboard the clipper ship 'Nightingale,' chartered by the Western Union Company, bound for Plover Bay, on the Asiatic side of Behring Straits, St. Michaels being on the American side.

"We arrived at Plover Bay in 1866 and were making ready for St. Michaels when a British bark arrived from Victoria, B. C., with the news of the successful laying and operation of the Atlantic cable.

"Our executive ordered us to return, and gave us instructions to notify the St. Michaels' party and the party on the Amoor River in Siberia, of which Mr. George Kennan, the well-known former telegrapher and noted writer, was a member.

"In August," Mr. Kearney continues, "we set sail for St. Michaels, and on reaching there delivered our instructions to the force in the interior.

"We then sailed for Petropaulovski, Kamchatka, where we delivered the instructions to the Kennan party, and then proceeded to San Francisco, reaching there on December 25, 1866."

After getting his discharge from the Collins Overland Service, Kearney received transportation from San Francisco by stage overland to St. Joseph, Mo., homeward bound.

On arrival at Denver, Col., he was intercepted and sent to Central City, Col., on relay duty, and from there he was ordered to Julesburg, then the western terminus of the Union Pacific Railroad. From Julesburg he went to Cheyenne, Wyo., where he opened the first Western Union line for business. Mr. Kearney remained in Cheyenne, and when the overland wires were abandoned at Denver, and Cheyenne was made the relay office between Omaha and Salt Lake City, he was placed on the relay force. He was on the night force in Chicago before and after the great fire, working the overland wire, and afterward returned to Cheyenne. Later he was detailed from the relay office at Corrine, Utah, to Promontory, Utah, to announce to the world the completion of the Union Pacific and Central Pacific railways.

Mr. Kearney was General George Crook's military telegrapher at Fort Whipple, Ariz., during the Apache campaign. After this service he spent sixteen years in the Ogden Western Union office, and then returned to Arizona, where he now resides.

An Example of Taste and Good Sense.

A correspondent of the *Railway Age Gazette* in discussing the issuing of circulars on "courtesy" by railway companies to their employes, refers to a circular of this character issued by Mr. E. J. Nally, vice-president and general manager of the Postal Telegraph-Cable Company, New York, as "an excellent example of good sense, brevity and refined taste." The circular which is thus complimented is as follows:

"THE EMPLOYE IS THE COMPANY.

"It is a fact that the public regards the representatives it meets and with whom it transacts business as the company itself. We know this from our personal experience in stores, for instance. If we are well treated by the clerks, if they are pleasant and affable, if they impress us by their alertness and their knowledge of their business, our trade naturally gravitates toward that store. We like to go there; we are glad to tell our friends about it and to influence their patronage in that direction. So it is with the representatives of the Postal Telegraph. The public receives its idea of the company largely through you. You are the ones they meet and from whom, as a rule, they form their impression of the company itself. Hence it behooves all to be efficient, alert, honest and obliging, since in so doing we not only build character for ourselves, but we likewise give character and reputation to the company we serve."

Every telegrapher should study the Lessons on Technical Telegraphy now running in TELEGRAPH AND TELEPHONE AGE. Subscription price, $2.00 per year.

ADDRESS ALL COMMUNICATIONS TO
J. B. TALTAVALL, - - - Publisher
253 BROADWAY, NEW YORK.
T. R. TALTAVALL, Editor.
R. J. WEEKS, Manager Advertising Department.

CABLE ADDRESS: "Telegage," New York.
Telephone: 6657 Barclay

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

January 16, 1912.

Lower Cable Rates a Step in Progress.

It has been pointed out that the low-cost cable business will add another link to the chain of civilizing influences and aid in cementing the bonds of amity between the nations. The railway, the steamship, the telegraph, the cable and the telephone have indeed worked wonderful changes in the world. These agencies are breaking down obstacles of every kind that impede progress and are in effect amalgamating the nations of the world into one brotherhood. The millennium has not yet come, however, and there is much to be done before the time is ripe for it. Change from existing conditions means progress, and it is simply in the line of advancement that the cable companies have taken this step. The question of expediency is another matter; the times demanded this new service and the companies have met the situation.

All innovations disorganize the regular schedule more or less until they finally fall in line and become a part of the machinery of the world's activities. The low cable rates will no doubt develop a large business of a new class, and it will be interesting to note the practical effects of the new idea.

Economy in Small Things.

"Save the pennies and the pounds will take care of themselves" is a trite saying, and, while every one admits the truth of it, few practice it. The average person is wasteful, not only of his own property, but that of others, and this is particularly true as regards small things. There is no reason why one should destroy or waste a brick any more than tear down a house, or destroy a message blank any more than destroy a pole line. The principle is the same in both cases, and yet needless destruction is continually going on all over the country.

Many large industrial concerns, including telegraph and telephone companies, have taken up in earnest this matter of waste-prevention, and figures have been prepared showing the saving that results from the practice of economy in little things. The exhibit is indeed a surprising one, and the figures, we think, will have the effect of encouraging all fair-minded persons to practice economy in the use of his employer's property. This is an excellent habit to form and it is based on good reason.

Another "Youngest Operator."

When the newspapers run short of thrilling news they turn their attention to more commonplace subjects, and the telegraph messenger occasionally comes in for a share of the glory.

Some months ago a young messenger in Tarrytown, N. Y., achieved fame—newspaper fame—because he abandoned his bicycle in the delivery of messages asserting that it was not fast enough. Now the same youngster—he is 14 years of age so the newspapers state—is said to be night operator at Tarrytown, and, as usual, "is the youngest operator in the employ of the company."

We are constantly receiving clippings about the "youngest operator." The woods and towns are full of them. Any one not knowing the facts would get the impression that the telegraph business of the country is run by babes. It would be a reflection upon the telegraph companies to let such absurd notions pass unchallenged.

Occasionally we read of a young boy being able to run a locomotive, but no railroad company employs him in the capacity of an engineer. Much more than the ability to send and receive messages is required in an operator; he must have sound judgment and be prepared to act promptly in emergencies.

Age Limitations.

With legal restrictions and limitations on the one hand and rules of corporations on the other the range of a man's usefulness these days is much narrowed. In many of the States stringent laws exist prohibiting the employment of persons under twenty-one years of age in certain lines of work, railroad telegraphy for instance, and many railroads have set the maximum age at which a person may enter the service at thirty-five years. Thus it may happen that a railroad company cannot legally employ a person under the age of twenty-one and by its own rules reject an applicant for a position who is over thirty-five years of age. Logically this limits a man's useful life to fourteen years.

The telegraph companies are also affected by the legal restrictions in many of the States, for they are prohibited from employing messengers under a certain age in night service, and although, as far as we are aware, their rules do not prohibit the employment of persons well ad-

Digitized by Google

vanced in years in any branch of the service, the tendency is to favor the younger men, which of course is very natural from a business standpoint.

The legal limitations must naturally have a tendency to discourage a young man who has ambitions to enter a vocation which may happen to be so restricted and drive him into some other line of work where he can find immediate employment.

Many of the railroad companies have pension schemes for the benefit of their employes and the officials advance the argument that it would be manifestly unfair to their employes who entered the service at the earlier ages to place on an equal footing with them those who are taken on at an age approaching the maximum limitation. It is right and proper that there should be reasonable restrictions placed upon the employment of young persons at too early an age, but it is an open question as to the wisdom of denying a man the opportunity to earn a living simply because he has reached the age of thirty-five years. So long as he is capable of filling the position he should be given the opportunity to do so whether he be thirty-five, forty-five or fifty-five years of age.

Holiday Greetings.

With deep appreciation and pleasure were acknowledge the receipt of holiday greetings from Mr. H. C. Wilson, in charge of government telegraphs and telephones, Jamaica, B. W. I.; Commercial Cable Company, New York; Mr. S. M. English, general manager of the Postal Telegraph-Cable Company of Texas, Dallas, Tex.; Mr. H. A. Tuttle, president of the North American Telegraph Company, Minneapolis, Minn.; Mr. W. J. Lloyd, division traffic superintendent, Western Union Telegraph Company, Chicago, Ill.; Mr. Earl W. Miller, chief operator, Postal Telegraph-Cable Company, Philadelphia, Pa.; Mr. W. C. Carswell, manager, Western Union Telegraph Company, Topeka, Kan.; Central Executive Association Irish Post-Office Clerks, Dublin, Ireland; "The San Francisco Western Union Force;" Mr. H. D. Rogers, retired old timer, Boston, Mass.; Mr. J. Frank Howell, broker, New York; Mr. J. D. McLelland, Houston, Tex.; Mr. T. W. Goulding, European general manager of the Western Union Telegraph Company, London, England; Mr. E. J. Nally, vice-president and general manager Postal Telegraph-Cable Company, New York; Mr. G. K. Heyer, general sales manager Western Electric Company, New York; Mr. J. B. Dillon, Western Union Telegraph Company, Dallas, Tex.; Mr. H. P. Trainor, electrical engineer of government telegraphs, Pretoria, South Africa; managing editor of the *South African Railway Magazine,* Johannesburg, South Africa; Samosuke Inada, of the Engineer's Section, Department of Communications, Tokyo, Japan.

The Origin of Public Utilities Commissions.—Mr. Arthur Stedman Hills, of the bureau of commission research, legal department, American Telephone & Telegraph Company, New York, delivered an address entitled "The Origin, Growth and Work of Public Utilities Commissions," before the Accountants' Theories and Talks Club, of the American Telephone & Telegraph Company, New York, November 15, 1911. The address has been reprinted in pamphlet form. Mr. Hills' investigations into the subject took him as far back as the year 1348, so it is evident that the public utilities commission idea is not new.

Electrical Instruments and Testing.

Every one connected with the telegraph and telephone service should know how to test lines and also be familiar with the instruments used in such work. It does not require much study to learn the mechanical operations of this important branch of the service, but of course a knowledge of electrical and mechanical principles involved in the design and construction of the instruments, and of the principles involved in measurements is the source of deep and never-ending pleasure to the ambitious student.

An excellent book on this subject, intended for the practical man, is "Electrical Instruments and Testing," by Norman H. Schneider, with new chapters on testing wires and cables and locating faults, written by Jesse Hargrave, division superintendent of the Postal Telegraph-Cable Company, Atlanta, Ga.

This work tells how to use the voltmeter, ohmmeter, ammeter, potentiometer, galvanometer, the Wheatstone bridge and standard portable sets. The apparatus described is modern and in universal use, and the tests are such as are required daily.

Mr. Hargrave carries the student step by step through the different methods of testing for faults, insulation and conductivity, cable faults, etc., and the simplest language possible is used. The formulas given are explained in the text preceding them, and examples are worked out in simple arithmetic.

This is one of the most practical and useful books on electrical testing instruments and testing that has been published and is fully illustrated with views and diagrams of instruments used in this line of work. Every one who desires to widen his knowledge on electrical matters should have a copy of this book in his library. Even if he never has the opportunity to make an actual test he will learn a great deal from the work that will improve his mind and general knowledge of things electric.

The price of this book is $1.00 and copies can be had of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York. Any other book on telegraph, telephone or general electrical subjects can be obtained at the same place.

Course of Instruction in the Elements of Technical Telegraphy—VII.

(*Copyrighted.*)

(Continued from page 9, January 1.)

[We began in our issue for October 16 the publication of a course of instruction in technical telegraphy. The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and is divided into chapters, following one another in logical order.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases, and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.

The mathematical section which is now running will carry the student through fractions, decimals, proportion, elementary algebra, etc.]

EQUATIONS.

An Equation is the algebraic expression of two equal quantities with the sign of equality placed between them. Thus, $x = a + b$ is an equation in which x is equal to the sum of a and b.

By the definition every equation is composed of two parts, connected by the equality sign =.

The part on the left of the sign is called the first member; that on the right, the second member. Each member may be composed of one or more terms. Thus, in the equation $x = a + b$, x is the first member, and $a + b$ the second.

Equations usually consist of known and unknown quantities, that is of quantities whose values are given and of quantities whose values are not given but are to be found. Thus, in $x + 6 = 14$, 6 and 14 are known quantities, and x is the unknown.

If equal quantities be added to both members of an equation, the equality of the members will not be destroyed.

If equal quantities be subtracted from both members of an equation the equality will not be destroyed.

If both members of an equation be multiplied or divided by the same number, the equality will not be destroyed.

TRANSFORMATION OF EQUATIONS.

The transformation of an equation consists in changing its form without changing the equality of its members. A common transformation is made by transposing certain terms from one member to the other, for which we have the following rule:

RULE (7). *Any term may be transposed from either member of an equation to the other if its sign be changed.*

Example 1. In the equation $3x + 5 = 12$ transpose the + 5 to the second member.

Solution. Changing the sign to —, and placing in second member.

$$3x = 12 - 5. \quad \text{Ans.}$$

Example 2. In the equation $3x - 5 = 12$ transpose the — 5 to the second member.

Solution. Changing the sign to + and placing in second member.

$$3x = 12 + 5. \quad \text{Ans.}$$

To solve a simple equation apply the following rules.

RULE (8) (a.) *Clear the equation of fractions by multiplying both members by the denominator of the fraction containing the unknown quantity.*

(b). *Transpose the unknown terms to the first member, and the known terms to the second member.*

(c). *Combine the terms of the unknown quantity by adding or subtracting.*

(d). *Divide both members by the co-efficient of the unknown quantity*

Example 1. $\dfrac{x \times 25}{x + 25} = 20.$

The numerator of the fraction becomes 25x, the sign × being omitted.

$$\frac{25x}{x + 25} = 20.$$

If we multiply the numerator of a fraction by its denominator and divide we obtain a quotient that is equal to the numerator. $\frac{1}{2} \times 2 = 1$; $\frac{2}{3} \times 3 = 2$; so that applying Rule (8) a; $\dfrac{25x}{x + 25} \times x + 25 = 25x.$

Multiplying the second term by $x + 25$ we get

$$20x + 500.$$

The equation is now $25x = 20x + 500.$

Applying rule 8, (b), we transpose the terms of the unknown quantity, or x, to the first member.

$$25x - 20x = 500.$$

Applying rule 8, (c), $5x = 500.$

Applying rule 8, (d), $x = 100$ Ans.

Example 2. $\dfrac{x \times 6}{x + 6} = 1\frac{1}{2}.$

By Rule (a) $6x = 1\frac{1}{2}x + 9.$

By Rule (b) $6x - 1\frac{1}{2}x = 9.$

By Rule (c) $4\frac{1}{2}x = 9.$

By Rule (d) $x = \frac{9}{1} \times \frac{2}{9} = \frac{18}{9} = 2.$

$x = 2$ Ans.

Example 3. Find the value of x in $\dfrac{x \times 10}{x + 10} = 8.$

Solution.

By Rule (a) $10x = 8x + 80.$

By Rule (b) $10x - 8x = 80.$

By Rule (c) $2x = 80.$

By Rule (d) $x = 40.$ Ans.

Example 3. Find the value of r in $\dfrac{15 \times r}{15 + r} = 6.$

Rule (a) $15r = 90 + 6r.$

Rule (b) $15r - 6r = 90.$

Rule (c) $9r = 90.$

Rule (d) $r = 10.$ Ans

QUESTION PAPER.

(1) Divide .004 by 400.
(2) Divide .0144 by .024
(3) Reduce .3125 to a common fraction.
(4) Express $\frac{5}{16}$ as a decimal.
(5) Find the product of .000492 × 4.1418.
(6) Find the sum of 1427.16, .244, .32, .032 and 10.0041.
(7) From 1.000014 take .00001.
(8) Find the value of R in
(a) 14 : R : : 6 : 2
(b) R : 24 : : 8 : 40
(c) 8 : 30 : : R : 20
(d) 4 : 6 : : 8 : R
(9) $\frac{100 \times 25}{100 + 25} = ?$
(10) $\frac{1}{2}\frac{1}{5} + \frac{1}{4}\frac{1}{5} + \frac{1}{7}\frac{1}{5} = ?$
(11) Divide 1 by $\frac{2}{7}\frac{3}{5}$
(12) Express as a decimal 1 ÷ 100.
(13) What is the effect of moving a decimal point three places to the left?
(14) Given a decimal .0321. If the point is changed three places to the right, thus, 032.1, what has been done?
(15) Find the value of R in the equation
$\frac{500 \times R}{500 + R} = 166\frac{2}{3}$
(16) Find the value of x in the equation
$\frac{x \times 5}{x + 5} = 3.75.$
(17) Multiply both terms of the equation
$\frac{E}{I} = R$, by I
(18) Find the least common denominator of 30, 25, 40, 1, 0.
(19) Find the sum of $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, $\frac{1}{8}$, $\frac{6}{6}$.
(20) Find the product of .00007 × 70000.
(21) Subtract $12\frac{1}{8}$ from 27.
(22) Subtract $\frac{1}{1}\frac{5}{6}$ from $\frac{5}{4}\frac{7}{8}$.
(23) What are similar terms of a polynomial? Are 3ab and bc similar?
(24) If no sign is prefixed to an algebraic term what sign is understood?
(25) Reduce the polynomial — 9cb + 8ac + 15cb + 8ca + 9ac — 24cb to its simplest form.
(26)
(a) Find the sum of

New Book.

"Telephonology," by H. R. Van Deventer. A new edition of this well-known work has just been published and is now ready for delivery. It contains 600 pages and over 600 illustrations, and measures 6 x 9 inches.

"Telephonology" is a practical work and has little to say on the theory of the telephone, devoting itself to data and description, and giving just the material the practical man needs. It has been carefully compiled from many different sources, each section being prepared under the supervision of an expert in that particular line. Exceedingly simple circuit prints were made especially for this book, the descriptions and instructions which accompany each print being clear and free from mathematics and technical language. A complete index serves to locate instantly any subject.

Following is a partial list of the subjects covered by this book: Erection, Equipment and Maintenance of Telephone Exchanges, Line Instrument and Switchboard Troubles and Their Remedies. Apparatus, Line and Cable Testing. Instructions for Locating Line Troubles, Cable Faults and Their Remedies, Testing Apparatus, Switchboard Circuits, Magneto and Common Battery, Phantom Circuits, Composite Systems, Harmonic Party Lines, Combined Telegraph and Telephone, Automatic, Wireless, etc.

Chapter 15 describes the various composite systems.

Chapter 16 is devoted to Wireless Telephony.

Chapter 17 treats of railway or train dispatching systems and describes in detail the principal makes of equipment, the circuits, etc. This chapter will be found of particular interest and value to those interested in railway work.

All of the earlier chapters have been carefully revised, and a new chapter has been added describing new apparatus, circuits and inventions for 1911.

From a general perusal of this work it does not seem that anything concerning telephony has escaped the author's attention.

The price of this book is $4.00 per copy and copies are for sale by TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

"Seagumite," New Insulating Substance. — A company has been formed in London to exploit a new insulating compound made from seaweed. According to a despatch from London, the new composition possesses special qualities as an electrical insulator, and will form a substitute for vulcanite. It is called "seagumite."

The Development and Present Composition of the Western Union Telegraph Company.

BY E. Y. GALLAHER, AUDITOR OF THE WESTERN UNION TELEGRAPH COMPANY, NEW YORK.

(Concluded from page 18.)

CO-OPERATION WITH ALLIED COMPANIES.

For the purpose of promoting co-operation and conserving our interests in the allied companies not leased, it was decided to extend the supervision of the auditor of the Western Union Company. Accordingly, I was elected auditor of the American District Telegraph Company of New Jersey, the American District Telegraph Company of New York, the Stock Quotation Telegraph Company and the Philadelphia Local Telegraph Company.

The American District Telegraph Company of New Jersey is composed of a considerable number of other companies, organized to meet state requirements, and is also affiliated with a number of allied operating companies. The company formerly conducted a messenger business in all parts of the United States, with the exception of the city of New York, but this messenger business, together with the plant, was leased to the Western Union Company as of January 1, 1911, under an operating agreement. The American District Telegraph Company's activities are now directed toward the installation and operation of signal systems, that is, burglar alarms, night watches, sprinkler systems, etc., and it is thought there is a wide field for the development of the business. The company has thirteen independent offices and about one hundred joint offices with the Western Union Company, a total of one hundred and thirteen.

The American District Telegraph Company of New York restricts its operations to the city of New York, where it is engaged in the distribution of parcels, etc., for merchants, and conducts a messenger business with a call-box plant.

The Stock Quotation Telegraph Company owns a large office building at Beaver and Broad streets, New York, and is principally occupied in furnishing ticker service and the dissemination of news, its active operations being largely in the city of New York, though it has contracts with companies in Boston and elsewhere for the interchange of business.

The Philadelphia Local Telegraph Company is a small concern, located in the city of Philadelphia, and holds valuable franchise rights, the Western Union Company controlling all of its stock.

PRESENT ORGANIZATION OF WESTERN UNION COMPANY.

On January 1, 1910, the Western Union organization in the United States consisted of a president and general manager, a vice-president in charge of contracts, a vice-president in charge of cable business, a vice-president and auditor, the treasurer and the secretary. The country was divided in four divisions, at the head of each of which there was a general superintendent, and under these general superintendents district superintendents to the number of twenty-three.

State lines were not adhered to in the separation between the divisions, and the districts were mixed, both as regards state lines and the boundaries of each other. The duties of the general superintendent and his district superintendents combined plant, traffic and commercial functions. In addition to the territorial organization, the company was operated under line organization as distinct from a staff organization at headquarters.

In reorganizing the company, it was thought some of the divisions contained too much territory for adequate supervision, and, accordingly, two new divisions were created, making six in all, these being known as the Eastern, Western, Southern, Gulf, Mountain and Pacific. The office of general manager and president was separated and a general manager appointed.

The Eastern Division, with headquarters at New York, consists of six districts, and comprehends the states of Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Delaware, West Virginia, the territory of New Brunswick, a part of Nova Scotia, and a portion of Canada between Lakes Huron, Ontario and Erie.

The functional organization has been reorganized by giving the general superintendent a division plant, a division traffic and a division commercial superintendent, and in each of the districts, except the second, there is a district plant, a district traffic and a district commercial superintendent; the second district, covering Jersey City, has only a district superintendent. The districts do not strictly follow state lines, but it is possible to block them out and show the lines of demarcation between them.

Following the district superintendents come the managers, who have nothing to do with plant, but combine traffic and commercial, and operate the Western Union offices open to the public. This arrangement is common to all divisions.

The Western division, with headquarters at Chicago, includes the states of North and South Dakota, Minnesota, Michigan, Wisconsin, Iowa, Illinois, Indiana, Ohio, Missouri and Arkansas.

This division is divided in seven districts and has the same organization as the Eastern division respecting division and district plant, traffic, and commercial superintendents, with the exception of the Chicago City district, which is supervised by a district commercial superintendent.

The boundaries of the districts, however, overlap one another to such an extent as to make it impossible to mark them on the map, some offices apparently logically within the territory of a district reporting to the superintendents of contiguous districts.

It is expected that this feature will be straightened out, as a number of reasons indicate the advantages of having districts that do not encroach on one another's territory and whose confines are within state lines.

Digitized by Google

The Southern division, with the general superintendent at Atlanta, is made up of the states of Virginia, Kentucky, Tennessee, North Carolina, South Carolina, Georgia, Florida, Alabama and Mississippi, and has four districts.

It was not considered advisable to extend the full functional organization to this division, and the general superintendent has a division commercial and traffic superintendent, and a division plant superintendent.

In each one of the districts there is a district superintendent supervising traffic and commercial matters, and a district plant superintendent, and each district also has a commercial superintendent, who is under the supervision of the district superintendent.

The Gulf division is composed of three districts, and includes the states of Texas, Oklahoma and Louisiana; these three states constituting the three districts. The organization of the general superintendent's office, located at Dallas, Tex., consists of a division commercial and traffic superintendent and a division plant superintendent, and each district has a district superintendent and a commercial superintendent, the division plant superintendent looking out for plant matters in the entire division.

The Mountain division is made up of three districts, which include the states of Montana, Idaho, Wyoming, Utah, Nebraska, Kansas, Colorado and New Mexico. The districts in this division are by state lines and the organization comprehends, besides the general superintendent at Denver, a division commercial, a division traffic and a division plant superintendent, and each district has three superintendents for commercial, traffic and plant, respectively.

The Pacific division has three districts, and takes in the states of Washington, Oregon, Nevada, California and Arizona. One of these districts is by state lines, the other two are not; yet, owing to the fact that the dividing lines between the last mentioned districts are comparatively easy to follow, no difficulty should exist in administrative and accounting matters. The organization of the division, with the general superintendent at San Francisco, is a division commercial superintendent, a division traffic and a division plant superintendent, and in each district are superintendents for these three activities.

THE COMPANY'S CABLE INTERESTS.

As I said before, the Western Union Company is operating under lease two cables belonging to the American Telegraph and Cable Company. In addition, it operates, under lease, a cable of the International Ocean Telegraph Company, which connects the mainland at Florida with Cuba.

A proposed agreement was ratified at the last stockholders' meeting by which the Western Union Telegraph Company has leased, for a long term of years, the four cables belonging to the Anglo American Telegraph Company, and the cable belonging to the Direct United States Cable Company, under an operating arrangement.

The Western Union built a fine cable during the year 1910, the largest in capacity ever laid, which is known as the Bay Roberts cable, and this, together with those leased from the Anglo and Direct companies, will give control of eight ocean cables, not counting the International Ocean telegraph cable to Cuba.

The business which will thus be absorbed is a large one, and the plans of the accounting department are to establish a division auditor in charge of cables, and, for the sake of simplicity, to maintain an entirely separate set of books for the cable business, enabling the auditor to prepare a balance sheet and earnings report which can be combined with the Western Union land line statements. I understand the operating department is considering the creation of a distinct organization.

The company has for years had its own offices in London, Liverpool and Penzance, where cable business has been exchanged with the British Post Office cable companies and the Continent. It has also maintained joint offices with the Anglo and Direct companies in nine cities in Great Britain, and has agencies in Paris, Antwerp and Naples. Our new relations with the Anglo and Direct companies will, of course, soon increase our active interests abroad.

ACCOUNTING CONDITIONS AND ORGANIZATION.

The system of plant accounting which the telegraph company should have in respect to work reports for handling material, the preparation of payrolls, etc., is not dissimilar to that adopted by the telephone companies, but consideration will naturally have to be given to the provisions contained in the many railroad contracts.

A real distinction exists, however, in the commercial accounting in the field. Broadly speaking, the telephone companies' worries are confined to the recording of subscribers' exchange and toll business, this being generally concentrated for billing purposes at accounting centers. We find accounting centers in the Western Union Company in large cities, where branch offices report to main office; for example, at Chicago the billing is done from the main office, but this plan has not been put in effect in New York.

The principal difference, however, between the accounting arrangements of the telegraph company and those of the telephone companies is that the telegraph company has some 3,700 independent offices, including branches, and each one of these offices is practically a unit in itself, conducting its own charge accounts and paying its own expenses.

Then again the offices are engaged in transactions other than straight telegraph business; for example, each manager is obliged to keep separate in his accounts Western Union telegraph revenue; telegraph revenue from other lines; cable revenue; revenue from sub-rents; time service receipts; commercial news business, which is subdivided under several heads; money order business, for which he has to report principal, premiums and tolls; miscellaneous domestic revenue; messenger revenue; half-rate business, and messages sent under franks, of which there are a number of different kinds.

Digitized by Google

His disbursements, on the other side of the account, comprehend paid other lines, refunds, uncollectible messages, railroad companies' proportion of receipts, the regular expenses of the office, pay of messengers, rents paid in cash, rents paid in telegraphing, etc., and, in addition, he is obliged to keep distinct the account with the telephone offices, United States Government messages, and prepare his check report. These accounting duties, which I have just enumerated, give you only a brief sketch of the many duties required of the manager, for he is also the operating man.

In the telegraph company's business, where the accounting is of a complex nature, and also expensive, by reason of its being multiplied by the large number of offices, we have a problem to meet in the way of simplifying the manager's accounting duties. When I said that the accounts were complicated, I meant relatively so, in view of the fact that a manager is not primarily selected for his knowledge of accounts; he may be an excellent commercial man, or an adept in traffic matters.

Many changes have already been made in the accounting methods which would take a long time to explain and would bore you considerably to listen to. Suffice to say that by alterations in the organization, the Check Bureau and Free Message, or Message Settlement Bureau, were annexed by the auditor. The Accounting Department at New York has been subdivided into a division of receipts and a division of disbursements, and these into bureaus and sections, with necessary controlling accounts.

It was decided to divorce the auditing and accounting so far as possible from the supervision of the district superintendents, and, to this end, six division auditors, one for each division, were appointed and installed at the respective division headquarters and now report direct to the auditor at New York. The plan is that the Accounting Department will furnish periodical reports of operations for the administrative needs of general, division and district superintendents.

By organizing adequate staffs of traveling auditors under the supervision of the division auditors, it is expected that much assistance can be given the managers regarding the keeping of accounts, and that the rendering of reports will be improved, both as to time forwarded, and the shape in which they are sent in.

The division auditors are at present engaged in transferring the auditing of managers' accounts from the offices of district superintendents to their own offices, and this proceeding connotes the transference of employes, records, furniture and everything pertaining to the work.

The next step, so far as field accounting is concerned, will be changes in the methods of accounting now obtaining at managers' offices, and the preparation of a handbook for their guidance, the main objects being to make methods uniform and simple, and to establish the system of depositing receipts and making disbursements from advance accounts.

It is then contemplated for the division auditors to take over as much of the accounting work as possible from the district superintendents, which includes leased wire, pole license and plant accounting, and install plant records at division headquarters so that finally each division auditor will render monthly a balance sheet and earnings report for his division, and these statements will be combined with the head office figures in the auditor's department at New York, subject to interdivision transactions, thus arriving at statements for the entire Western Union Company.

The treasurer is considering appointing a division cashier for each division except the Eastern, at the headquarters of which he is himself located. When this plan, or one designed to afford the same facilities, is accomplished, each division will have the component factors to make it a unit in itself, subject to control exercised from New York.

About a year and a half ago we prepared a classification of accounts, but its issuance was held up pending the passage of the law which became effective August 17, 1910, vesting supervision over telegraph companies in the Interstate Commerce Commission. This action on the part of the federal authorities was followed almost immediately by similar laws from a number of the states, and conferences have been held with the Interstate Commerce Commission and the Public Service Commission relative to the promulgation by them of classifications of accounts for telegraph companies.

In view of the fact that it would take some time to install a classification of accounts for the Western Union Company, it was thought wise to hold the matter in abeyance until the Interstate Commerce Commission had issued its classification, which was received on November 29 last, with the statement that it would be operative January 1, 1912.

Fungus Growth on Rubber Insulation.—The *India Rubber World* refers to a fungus growth which sometimes appears on rubber insulation. This growth takes place sometimes, even when the insulated wires are inclosed in a conduit of enameled iron. The fungus growth, which destroys the insulation, is promoted by iron rust, which, with the consequent fungus growth, is impossible except where there is some moisture. The remedy therefore is to insure the dryness of the tube interior by blowing hot air through it, and then all future possibility of dampness must be prevented. If it is impossible under the circumstances to keep the inside of the tube dry a good quality of red lead paint is the best preventive of damp and fungi.

Panama Trip of Electrical Engineers.—Over one hundred members of the American Institute of Electrical Engineers will make a trip of inspection to the Panama Canal. The New York contingent will sail on the steamer "Almirante," January 17, and the steamer "Parismina" will sail from New Orleans, January 20, with those who prefer to take that route.

The Tribulations of A Military Telegraph Operator.

BY DERICK H. FITCH, OF CAZENOVIA, N. Y., MEMBER SOCIETY UNITED STATES MILITARY TELEGRAPH CORPS.

When General Price made his last raid to the North, in 1864, he was for a time in possession of the Missouri Pacific Railroad, east of Jefferson City. He cut all wires, hence communication with the state capital was suspended.

The only way to reach that point was to go on the North Missouri Railroad to Mexico, Mo., and then across the country. This caused a very unusual demand for transportation on the road where I was serving.

Someone at headquarters conceived the idea, that in order to save the capital, Gen. Pleasanton must go there and take command. About eleven o'clock one night I got orders to furnish transportation for him, and an escort of sixty cavalrymen.

It so happened that we had no cars south of the river suitable for horses. We had to get up steam on the ferryboat, take them across the river and to St. Louis, twenty miles.

His train consisted of two coaches for himself, his staff and escort, six cars for horses, and one or two for accountrements. When he got to St. Charles, it was daylight. As our boat could carry only two coaches, or four cars, at a trip, some time was consumed in getting the train across the river. The General was in a rage, called us all kinds of rebels and said the delay had been intentional.

Then he called for the conductor; said he wanted to give him his orders. I said, "General, it has been the custom here for train men to get their orders from me." He made no reply to this, but asked, "Are there any other trains on the road?"

I replied, "Yes, there are several." He said, "Telegraph and stop all of them." I said, "General, I cannot do that—some of them are as important as yours: if you let me guide yours as well as them, they will not be in your way."

Then he told his adjutant to arrest me, take me to the office and see that I telegraphed to stop all other trains. The adjutant, a harmless little fellow, called out half a dozen men armed with Colts revolving rifles. I was armed with a little bucket of milk for my breakfast. I was boarding in the office then, and had no use for sleeping apartments.

I said, "General, is your adjutant an operator?"

"No!"

"Then how can he tell what I telegraph when we get there?"

His rage was an improvement on what it had been. "Sir," he said, "will you obey my order?"

I said, "General, am I under arrest?"

"Yes, sir."

"Then I cannot. Army regulations do not permit me to do duty while under arrest."

The adjutant and the guard went into the cars. So far as I know, I am under arrest yet.

Then he ordered the conductor on to the rear platform and put a guard over him, and also a guard on the engine, and said, "Proceed!" Well, in order to prevent accident I made great haste then to obey his order and stop all trains within his range, except one, in charge of Conductor Ackert, which I thought I could move safely.

When we had any reckless running to be done, Engineer Vade Eans wanted to do it, and this morning we complied with his wish.

It was evident that he was in sympathy with the General's haste, for the way they passed telegraph stations made me shudder.

Warrenton, forty-two miles out, was passed in little more than an hour: nearly double the speed of our passenger trains, when we had any.

I judged that they could not possibly get to Wellsville before 11.30 a. m.; in fact, I doubted if they would get there at all, at the rate they had been going, with rolling stock and track unfit for such speed. So I gave the operator at Wellsville an order to stop and hold the train until that time unless Ackert's train had arrived, and gave Ackert until 11.30 a. m. to run there, which he could easily do.

Engineer Eans got in sight of Wellsville a few minutes after eleven, saw the signal, and blew the whistle for brakes.

"What is that for?" inquired the guard. "There is a signal to stop for orders," said Eans. "Never mind that; go ahead!" "All right," said Eans, "but you will soon know what that green flag is there for."

He did not leave Wellsville at forty miles per hour.

There was a curve a little way west of the station, and beyond there the track was straight and level for many miles.

The engineers of the two opposing trains saw each other in ample time to stop. When they came near together General Pleasanton ordered Ackert arrested and asked why he was in his way. Ackert showed him his orders.

"What time is it now?"

"Eleven ten," said Ackert.

Then he arrested the engineer; his orders were of course an exact copy of Ackert's. Then Pleasanton ordered them to back up.

Ackert, a native of Missouri, with some of the frontier grit, said, "No, sir; I have got orders which give me this track until eleven thirty; I have only three miles to run, and fifteen minutes yet to do it in, and I am going there or stay here."

Pleasanton went into his car and permitted his train to be backed up to Wellsville.

When "Old Pap" Price got near Jefferson City, he found that the officers there had made such provision for defence that he thought it prudent to "pass by on the other side," and was many miles away when Pleasanton got there; but the latter was in time to "assume command" and "capture" a few disabled cannon which Price had left behind.

When I next saw Eans I asked him if he was not afraid to run so without orders. He said he was, until after he passed the first telegraph sta-

Digitized by Google

tion, and then he knew that if I could not give him a clear track, he would find signals to stop for orders, and he would have obeyed them in spite of his guard.

He would not have passed Wellsville if he had not a long straight track ahead. He wanted to show them what fools they were.

Major General Pleasanton's order to "proceed" did no harm. What would it have done if the telegraph line had failed?

Newark's First Telephone Exchange.

The *Sunday Call*, of Newark, N. J., for December 3 prints an interesting article on the first telephone exchange in that city. Mr. John J. Ghegan, president of J. H. Bunnell & Co., New York, was the manager of the exchange. It was established in 1878 and was under the protection of the Western Union Telegraph Company. Mr. Ghegan tells some interesting facts regarding his early experiences in the telephone business. One of his many duties was the soliciting of business. One Newark manufacturer well known for his enterprise laughed at the idea that the "scientific toy" could ever take its place among the business utilities.

"That's no good," he said to Mr. Ghegan. "You can't work that here."

Mr. Ghegan needed names for his list and he would never give up any prospective customer till every argument had been exhausted. This particular doubting Thomas listened good-humoredly enough while Mr. Ghegan set forth at length the particular reasons why the telephone was destined to play an indispensable part in the affairs of business.

"Well," said the manufacturer with a laugh, "you're a good talker anyhow. I'll tell you what I'll do. When you get a hundred names come to me. But you'll never get 'em."

"I got them all right," said Mr. Ghegan, "but before I did I had that man's name on the list."

"I guess the laugh's on me," he said, as he handed in his order for a telephone.

"In the early days of the telephone business in Newark," Mr. Ghegan said, "telephones were not listed by number. When you wanted the Murphy Varnish Company you called for the Murphy Varnish Company.

"You might suppose," said Mr. Ghegan, "that this was a rather unwieldly system. But when we decided to change to numbers there was an awful kick. I remember one eminently respectable old manufacturer got fairly blue in the face when he called for his place of business by name and the central insisted on the number of the telephone. I got the effect at my end and I heard about the scene at the other. We had a pretty tough time of it before we could get people to call for numbers. Our office had about 150 subscribers when we made the change."

Referring to his experiences in introducing the telephone in Mexico Mr. Ghegan says: "We discovered something about Mexican women. They had nothing to do, apparently, except to talk all day or listen all day. With such conditions there was no possibility of giving anything like an efficient service. It was a serious problem, but we solved it. We put in a push button on each side of the telephone. In order to use the line it was necessary to shove in one of the buttons. This grounded the line there and cut off service on the one side or the other of the place where the telephone was located, and when the women cut in to listen the talk would stop. It was a hardship for them, of course, for it deprived them of their chief source of amusement, but we were running a telephone company, not a long-distance entertainment bureau."

Mr. Ghegan, who is a member of the Telephone Pioneers of America distributed a reproduction of the first printed list of subscribers of the Newark exchange at the recent meeting of Pioneers in Boston.

Creating Business.*

BY H. L. CLARK, MANAGER WESTERN UNION TELEGRAPH OFFICE, MARIETTA, OHIO.

The company that renders good service, creates a demand for the service and advertising is one of the greatest creators of business.

In the telegraph business there is no better advertisement than a prompt, reliable service. A satisfied customer is a standing advertisement and a creator of business. Publicity and education are great factors toward creating business. When a new service is inaugurated it should be given all the publicity possible, and the public educated to use it.

The specialized blank is another good business creator, both for the customer and telegraph company as it acts as a salesman for the customer and creates business for the telegraph company. As this is an era of business-creating and new service, I wish to suggest another service which might appeal to the public and act as a sort of fill-in, although it might not be practicable. The same, no doubt, was said of the Day and Night Letter service before they were tested and found to fill a "long felt want." I suggest what might be called the "Mailogram," a five or ten word message, filed at any time before midnight at one-half the standard tolls for a ten word day message, no tolls less than fifteen cents, to be mailed at destination for delivery the following morning. This would be a compromise between the two services and answer the purpose for those who do not wish a long night letter and might be the means of creating a new field of business.

*From "Seventh District Blue Book."

Every one engaged in telegraphy and telephony should be a constant reader of TELEGRAPH AND TELEPHONE AGE. It gives the latest news in both these fields. Subscribe now. Subscription price, $2.00 per year.

Life of a Storage Battery.

BY FRANK M. EWING, ASSISTANT MANAGER TELEGRAPH DEPARTMENT, PENNSYLVANIA RAILROAD COMPANY, SOUTH WILLIAMSPORT, PA.

There is a great difference in opinion and experience regarding the life of a storage cell. The life of the cell depends very much upon how closely it is worked to its rated capacity as well as upon its mechanical construction. Some claim that when worked to an average of eighty per cent. of its full capacity it is safe to count on two years' service without any attention, except to occasionally add a little water to replace evaporation, while others assert that some storage batteries have been in use for over three years without other attention than to add water occasionally in order to keep the tops of the plates covered.

The quality of water used for storage cells is an important matter. In some localities the water is very injurious to the elements of storage cells, tending to shorten their life. It is essential that the acid and water be free from impurities, such as iron, arsenic and nitric or hydrochloric acid. In selecting sulphuric acid none but the sulphur or brimstone acid should be used; acid made from pyrites is liable to contain impurities, such as iron or arsenic. In places where pure water is not available only distilled or rain-water should be used.

Although storage batteries do not store electricity, they store energy by converting the kinetic energy of the electrical current into chemical potential energy, which is available as kinetic energy. The efficiency of the accumulator (or of any other means of storing or transforming energy) is the output divided by the input. This quotient is always less than one, as the accumulator is not a perfect storer of energy. There are certain losses in the transformation of kinetic electrical to potential chemical energy, and vice versa, besides the loss of the energy required to force the current through the cell, i. e., the loss due to the resistance of the plates and electrolyte.

I find from my experience in handling the Type E chloride accumulators which are used for telegraph and telephone work, that when they are not discharged at an excessive rate, nor to a lower electromotive force than 1.9 volts per cell, the positive plates last for about 1,200 or more discharges; while, if discharged each time below 1.8 volts per cell, or at an excessive rate, the life of the positive plates will not be more than 400 or 500 discharges. The negative plates, with good care, will usually outlast four or five sets of positive plates. The cells under my care last between four and five years, which is considerably longer life than is given in the various ratings, and only require the addition of sufficient water to replace evaporation and keep the tops of the plates covered at least ½ inch. Between the fourth and fifth year of service the positive plates become distorted which effect is known as buckling, and they crumble to pieces.

The cause of buckling seems to be the formation of sulphate in the plugs of active material which fill the spaces of the grids, thus causing the plugs to expand; lead having very little elasticity, the grid is forced out of shape. As usually constructed, the edges of the grid are heavier than the intermediate portion, so that the effect of the distortion is to bulge the plate in the center. If the plates are not discharged too far and too rapidly, the expansion of the active material is gradual, causing the grid to stretch evenly; this makes the plates "grow" or increase in area, sometimes as much as ten per cent.

Unless a battery is properly looked after, sulphating is liable to set in, and if allowed to proceed too far may cause much trouble. Lead sulphate is formed during each discharge of a cell, but this sulphate does no harm; in fact it is essential to the operation of the cell. However, under certain conditions a white insoluble sulphate may be formed, and it is this that causes the action known as sulphating. When a cell is sulphated, the plates, particularly the positive, become covered in spots with this white insoluble sulphate, which is difficult to remove. As the sulphate usually accumulates in patches, and as it prevents to a large extent chemical action on the active material underneath it, the capacity of the cell is reduced and the uneven action is liable to lead to buckling, unless the mechanical structure of the plate is such that buckling is practically impossible.

The most frequent causes of sulphating are overdischarging, strong specific gravity of the electrolyte, and allowing the battery to stand for a considerable length of time in a discharged condition. If a battery is looked after, as it should be, there will be no trouble from this source. If cells are repeatedly discharged below 1.7 volts, sulphating may be expected. At the end of a complete charge, a lodgment of white powder, that may easily be brushed off, will sometimes be noticed on top of the plates, provided the body of the plates are the proper color (positive, dark brown and negative, slate color). No attention need be paid to this powder as it is composed of particles from the plates thrown off by the gassing at the end of the charge. These particles become sulphated and of a light color while in suspension in the electrolyte.

In case white insoluble sulphate appears on the plates, the battery should be given a long continued charge at a low rate, somewhat below the normal eight-hour rate, until the cells give all the signs of a full charge and the plates have resumed their normal color. In case of badly sulphated cells, the color of the positive becomes lighter than normal and the negative considerably darker.

There are several kinds of treatment that will injure the cells. Among these is the habit, (which should never be permitted,) of connecting the terminals through a small resistance, or short wire, to see if the battery is in working

Digitized by Google

order, or how much of a spark it will give. A current of great magnitude will flow for a moment and it will likely loosen the paste and cause sulphating in the cell. Either a voltmeter or an incandescent lamp of known voltage should be used to determine the condition of the battery.

A complete charge should exceed the previous discharge, in ampere hours, from twelve to fifteen per cent. The principal indications of a complete charge are:

(1) The voltage and specific gravity reach a maximum value, which value is not necessarily fixed; for example, the voltage at the end of a charge may be from 2.4 to 2.7 volts. In the battery under my care the specific gravity always stands at 1,200 degrees and falls to 1,190 degrees on discharge.

(2) The amount of gas given off at the plates also increases when the cells are fully charged. Nothing is gained after the plates commence to gas freely, and it has been my practice to cut the charging current off when this action takes place.

(3) The positive plates become a dark brown, and the negatives a light gray.

(4) With all the cells of the battery in normal condition, with pure electrolyte and no material lodged between the plates or sediment touching them at the bottom, the maximum voltage and specific gravity are reached when, with the charging current constant at the normal rate, there is no further increase in either during a period from one-quarter to one-half hour. For example, if the charge has been carried on for eight or ten hours with a gradual rise in the voltage and specific gravity during that time and with an additional one-half hour of charging there should be no further rise in either, then the charge is complete. When a storage cell has the electrolyte covered with paraffin oil, there may be at any time a thin white froth on top of the oil, but when this froth develops rapidly to a depth of one-quarter inch, the cells are charged sufficiently. Care should be taken to keep the plates immersed in the electrolyte more than half an inch above the top of the plates. A storage cell will not attain its maximum capacity until it has been subjected to from ten to fifteen discharges, but will have at first about three-fourths of its maximum.

In order to secure satisfactory operation of a storage battery each of the cells should be inspected at regular intervals. It has been my practice to inspect the cells every day and watch them carefully while they are being charged. The voltage of individual cells may become low, the electrolyte may not be of the proper specific gravity, or foreign substances may become lodged between the plates or in the bottom of the cell, and regular inspection is necessary to locate any such defects that may develop.

For the inspection of individual cells, a portable lamp should be used so that any tendency for an accumulation or lodgment of material between the plates can be at once seen. If the elements are in glass jars, an ordinary lamp with extension cord to attach to the electric service wires will be found most convenient; by holding the lamp behind the jars and looking through between the plates the condition of the cell can at once be determined. When examining a cell great care should be taken to look between all the plates, and any accumulation of material should be removed at once. A lighted match should never be used to examine cells as there is danger of igniting the gas thrown off while charging. There have been cases where explosions were caused with a lighted match. If there is an accumulation of sediment from the plates themselves, it may be pushed down to the bottom of the containing vessel by means of a stick of hard rubber or wood; if it is any foreign substance it should be removed from the cell. A metal rod should never be used for removing obstructions in a storage cell; it is sure to cause short circuits and do damage.

In addition to the examination of the cells with the lamp, an examination should be made near the end of each charge to see if all the cells are gassing equally and freely. If any of the cells show readings lower than normal and do not gas freely at the end of the charge they should be examined at once with a cell lamp to determine the cause of the falling off. Very likely it is due to short circuiting between the plates, caused either by a lodgment of material in the intervening space or else by an accumulation of sediment in the bottom of the cell.

The life of a storage battery is much longer when it is installed in glass jars on account of permitting the examination of the condition of the plates while the cells are in operation. A thorough inspection cannot be made while the cells are in operation when enclosed in hard rubber vessels and lead-lined wooden tanks. Of course glass jars cannot be used for automobiles or coach lighting on railways because they cannot withstand rough usage and constant jarring, which ability is of more importance than long life for this class of service.

During my nine years' experience in handling storage batteries only one trouble developed that I did not understand. After the cells were cleaned and put in commission again, I discovered that the negative plates would gas as much and freely on discharging as they did while charging. In a short time a large amount of black substance resembling crude rubber formed in the bottom of the cells, in about six or seven hours the battery would play out after giving it the regular charging rate. I could find no information upon a trouble of this nature and those who had experience in handling storage batteries were equally puzzled. They all suggested giving an over charge; the specific gravity was run up to 1,250—fifty degrees above normal, but the trouble still remained and was not removed

Digitized by Google

until new negative plates were installed. The trouble was caused by the negative plates being exposed in the air too long while the battery was being cleaned, although the men were cautioned to keep the plates in a jar immersed in water while cleaning them. The plates had been in service six years when this occurred.

New Book on Telephony.

Modern American Telephony, In all its Branches. Edited by Arthur Bessey Smith. Published by Frederick J. Drake & Co., Chicago.

Telephony in all its branches is a large subject to cover in one volume, but the editor has succeeded very well in producing, in this case, a book that will be of particular interest to the student and the beginner in telephone work, as well as to the technical telephonist. It is very comprehensive and should meet with much favor among the classes of persons mentioned.

The scope of the book will be better appreciated by giving a list of the subjects of the chapters:

The Invention and the First Principles of the Telephone. The Installation, Operation, and Maintenance of Telephones; Including Electro-motive Force—Sound and Sound Waves. Induction, Strength and Direction of Induced Currents. Direct and Alternating Electrical Currents. Pressure, Resistance. Capacity. Magneto System—Transmitter. Magneto Generators. Batteries. Common Battery Systems. Power Plants for Common Battery Systems. Magneto Switchboards. Switchboard Installation. Multiple Switchboards. Common Battery Non-Multiple Exchanges without Central Office Connections. Test Boards, Distributing Boards, Testing Apparatus. Protective Devices. Measuring Instruments, The Wheatstone Bridge. Telephonic Troubles, How to Find and Remedy Them. Line Construction. Rural Line Construction. Electrical Conduit Construction. The Latest Automatic Systems. Wireless Telephony, etc., etc.

The book contains 790 pages and 470 illustrations, the diagrams being in the main clearly executed and helpful to a correct understanding of the subject they are intended to elucidate.

The chapter on wireless telephony will be found very timely. It gives a history of this branch of work and describes the various systems so far developed.

Automatic telephony, which is receiving much general attention at the present time, is also well presented and complete.

The book does not confine itself to a description of any one make of apparatus or any one system, but is universal, all practical systems coming within its attention. It is a good general review of the entire field of telephony and cannot fail to be of use to every one who has a desire to know things, whether he is in the telephone business or not, but it will be especially useful to the telephone man.

Copies of this book may be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York, at $2.00 per copy.

Industrial Democracy or Monopoly?

Mr. William W. Cook, general counsel and trustee for the Mackay Companies, New York, is the author of an article in *McClure's* for January under the title "Industrial Democracy or Monopoly? How American Railways Can Be Taken Over for the People Safely and Easily." It is a very comprehensive view of the railroad problem in relation to the public. "The railroad and corporation question," he states, "is still acute, as it has been for twenty years. Today it is intensified by the concentration of railroad power and bank power in the hands of Wall Street capitalists. It is a contest of political democracy with concentrated capital. The question is, Which shall control the nation?

"The American people," Mr. Cook continues, "believe in competition. But the trouble is that competition has been giving way in all directions. This is an age of consolidation, natural, irresistible and inevitable—consolidation of railroads and of all classes of industrial companies. Statutes may prohibit it and courts may denounce it, but it cannot be stopped any more than the tides. It is inevitable because it reduces cost, controls prices and makes more money. Great consolidations are here to stay."

Touching upon "Holding companies," Mr. Cook says: "The holding company, when properly used, is a lawful and very workable mode of organization. It is the latest, most useful and highest development of the corporation. And the corporation is a wonderful mechanism. The holding company is capable of infinite uses as well as great abuses. It is admirably adapted to the ownership and management of railroads, and, in fact, all great properties. It is my belief that this excellent instrument should be taken from the hands of Wall Street and placed in the hands of the people; that it be used for the formation of a new industrial democracy."

No Strike of English Operators.—Mr. Herbert Samuel, postmaster general of Great Britain, stated in the House of Commons recently that he did not think that there had been any probability of a strike of post-office officials. "Any uneasiness which may have existed," he said, "is already allayed."

In renewing thirty subscriptions going to chief train dispatchers and managers to that number of offices in the Southern Railway System, Mr. W. H. Potter, superintendent of telegraph, writes: "Your paper is very interesting and I believe the information contained therein has and will continue to be of considerable value, especially to those engaged in telegraph and telephone work. The series of articles you are now running on telegraph and telephone engineering promises to be of considerable value to those who will give the subject proper study."

Every one connected with the telegraph and telephone services should read Telegraph and Telephone Age. Its columns contain the latest news in these fields.

Telephony and Wireless Telegraphy Before the Turin Electrical Congress.

At the recent international electrical congress held at Turin, Italy, Mr. Frank B. Jewett presented a paper in which he described long-distance telephony in America. He stated that about 2,000,000 wire-miles of long-distance telephone lines are in use. Of this total wire mileage about 80 per cent. is in the form of open-wire circuits, on 168,000 miles of pole line, and the remainder is in cable circuits, principally underground. In addition to the equipment used exclusively for long-distance business, the equipment for exchange service and for connecting individual subscribers with the toll system comprises about 9,700,000 miles of wire. Practically all of the open-wire mileage is in the form of hard-drawn copper metallic circuits, many of which are equipped with Pupin loading coils. The copper wire ranges in weight from about 102 pounds per wire-mile to 430 pounds per wire-mile, the most common size weighing approximately 173 pounds per wire-mile. Many of the open-wire circuits are arranged to secure a third talking circuit from two metallic circuits by the phantoming process. The arrangement of open-wire circuits for phantoming is being extended with great rapidity, and with the more intimate development of a combined commercial telegraph and telephone system the compositing and simplexing of total circuits for simultaneous telephone and telegraph operation is being generally applied to all long-distance lines. Whether the wires employed for long-distance circuits in cables are large or small, they are invariably equipped with Pupin loading coils. The same is almost invariably true of all cable circuits employed for bringing open-wire toll lines into cities, whenever the length of such cable circuits is sufficient to warrant the use of loading coils.

Prof. P. O. Pedersen briefly outlined the different methods employed or proposed for increasing the degree of secrecy in wireless communication. A method devised by Mr. M. A. N. Hovland, a Norwegian naval officer, provides for automatic transmission in secret characters, the sender and the receiver being arranged to translate automatically from the usual to the secret characters and *vice versa*. This system permits a comparatively high speed of transmission.

A paper by Mr. H. Milon dealt with the advisability of using automatic and semi-automatic telephones in large cities. He briefly described the mode of operation of the manual, the automatic and the semi-automatic, and then proceeded to a comparison of the three systems on the score of quality of service and economy of operation. The author stated that while all telephone experts are not in accord regarding the relative merits of these various systems, it is doubtless true that the future will see a continual improvement and simplification of the automatic systems, while the recruiting of good operators will in all probability become more and more difficult as social conditions improve.

A brief résumé of the present state of development of wireless telephony was given in a paper by Dr. Valdemar Poulsen. The inability to construct a microphone capable of handling comparatively large amounts of energy constitutes the only present limitation of transmission distance. With a suitable microphone it would be feasible with present apparatus to transmit wireless telephone messages over the same distances now employed in wireless telegraphy. One distinct advantage of wireless over ordinary telephony lies in the fact that the timbre of the voice is not changed with distance; therefore the use of suitable relays offers great practical possibilities. One of the disadvantages of wireless telephony is the inability to receive messages at a station simultaneously with the sending of messages from the same station. Indeed, an attempt to do so will probably result in the destruction of the microphone. In its present state of development wireless telephony may be used commercially for distances up to 100 km. (62 miles) or 200 km. (124 miles).

Telegrapher's Cramp.—As already announced in these columns, the British post-office authorities reported recently on their investigations into the causes of telegraphers' cramp. After giving some statistics as to the percentage of operators afflicted, the report goes on to say: "The arduous and exacting nature of a telegraphist's work was put forward as a cause of cramp by the Postal Telegraph Clerks' Association in their evidence before the Industrial Diseases Committee in 1908. To show the physical and mental strain of the work upon an operator, it was explained that in sending at the rate of twenty-five words a minute 22,500 clearly defined signals per hour had to be made. The figures were said to be not uncommon, though they amount to seventy-one messages an hour; and it was contended that so unnatural and continued a stress could result only in nervous and physical deterioration. To make matters worse, the Post Office was said to be urging the staff to a greater and greater output of work, and the increased pressure on the operators had resulted in an alarming increase in the number of cases of cramp." The recommendations of the committee are: The admission into the service of fewer unsuitable learners; the more uniform tuition, under close and careful watching, of those who are admitted; the more rigorous protection of young workers from conditions of undue stress; the steady substitution of mechanical forms of sending for the finer muscular movements demanded by the Morse instrument; and the discovery and use of fresh forms of variation and relief for operators.

Convention of Electrical Engineers.—The next annual convention of the American Institute of Electrical Engineers will be held at Boston, June 25-28, inclusive.

The Railroad.

Mr. C. S. Rhoads, superintendent of telegraph of the Big Four System at Indianapolis, Ind., was in Florida recently on a vacation and he reports finding delightful weather and having a good time.

Mr. W. F. Williams, superintendent of telegraph of the Seaboard Air Line, Portsmouth, Va., and Mrs. Williams announce the marriage of their daughter Alma to Mr. Eugene Norfleet Davis on December 28, 1911. Mr. and Mrs. Davis will reside in Aberdeen, Miss.

Mr. P. E. Clark, general superintendent of the Lackawanna Railroad, at Scranton, Pa., has been appointed assistant to the president of that road, and Mr. E. M. Rhine has been appointed general superintendent to succeed Mr. Clark. Both Messrs. Clark and Rhine were former telegraphers, Mr. Clark being in the military telegraph service during the Civil War.

Railway Signal Association.—The proceedings of the annual convention of the Railway Signal Association held at Colorado Springs, Col., October 10-12, 1911, have just been issued in book form. The volume contains 636 pages, and a vast amount of information of general interest to railway men. Mr. C. C. Rosenberg, Bethlehem, Pa., is secretary of this association.

Association of Railway Telegraph Superintendents.

The committee of arrangements for the next convention of the Association of Railway Telegraph Superintendents, which is to be held in New York June 24, expects to soon make an announcement as to the plans for the convention, headquarters, entertainment, etc. It is intended that the arrangements shall not lack in any detail, and the committee feels confident that the New York convention will be one of the most successful ever held by the association. Mr. L. S. Wells, electrical superintendent and superintendent of telegraph of the Long Island Railroad, New York, is the chairman of the committee of arrangements.

Mr. Wells will be absent from New York for a few weeks, during which time Mr. L. B. Foley, superintendent of telegraph of the Lackawanna Railroad, New York, will act as chairman of the entertainment committee.

Retirement of Superintendent E. A. Smith.

Mr. Edgar A. Smith, assistant superintendent of the Boston & Maine Railroad, Fitchburg Division, Boston, Mass., has been retired from active service by the company taking effect on January 1, and the authority of Mr. J. D. Tyter, assistant superintendent, has been extended to cover the entire Fitchburg Division.

Mr. Smith was one of the best-known and most popular railway telegraph superintendents in the country and is familiarly known as "Smith of Boston." He was manager of the Western Union office in Fitchburg, Mass., between 1868 and 1870, when he entered the service of the Fitchburg Railroad. He passed through several positions and finally became superintendent of telegraph in 1890, which position he held until the Fitchburg Railroad became part of the Boston & Maine system. During his varied experience Mr. Smith was a passenger conductor for some time, and E. A. Smith Division 146, Order of Railway Conductors, was named after him.

The Turner Monument Fund.

The bronze tablet for the Turner monument which is on exhibition in the window of the Gorham Manufacturing Company, Fifth Avenue, New York, has been inspected by a large number of telegraph people and the general opinion is that it is a model of artistic skill and an excellent example of bronze casting. All those who are interested in the monument project, and who can find it convenient to do so, are advised to go and see the tablet as it affords a good subject for study.

The remittance of $10 from Mr. J. J. Ghegan, acknowledged in our issue for January 1, was in addition to that gentleman's previous contribution of a like amount. This makes $20 in all received from Mr. Ghegan on this account.

The total amount received toward defraying the expenses of the monument is $1,776.99.

Mr. J. B. Taltavall, 253 Broadway, New York, is the treasurer of the fund and will be glad to receive subscriptions from those who have not yet contributed and who wish to be identified with this historical movement. Subscriptions are acknowledged in the columns of TELEGRAPH AND TELEPHONE AGE, and the funds are deposited in the Washington Trust Company, New York.

Telegraph and Telephone Facilities On Governors' Special Train.

The Western Governors' special train which covered the eastern states in December was fitted out in every way possible with telegraph and telephone facilities. While at Philadelphia three direct line telephones were installed on the train and a uniformed attendant looked after the local and out-of-town calls. A 30-foot pole had to be erected especially to connect the train with the nearest junction box.

Mr. C. A. Crane manager of the St. Paul, Minn., Western Union office was designated by commercial superintendent A. D. Bradley, Minneapolis, Minn., to represent the Western Union Telegraph Company on the special throughout the trip. The fact that the Governors and train management passed unanimous resolutions thanking the telegraph company for manager Crane's services, shows that his duties were fulfilled in an eminently satisfactory manner. A large amount of full paid message business was handled from the train as well as a large press file.

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. There is a general demand for knowledge on the quadruplex, duplex, etc., and to aid in the acquirement of such knowledge we are extending our help to students by asking questions on these subjects in each issue of our journal, so that they may be encouraged in their studies by answering them. We use as our text-book Maver and Davis' "The Quadruplex," and students should have a copy of this book at hand in order to be able to give the answers. The questions are progressive and a careful reading of the book on the points under inquiry unfolds the answers. This method of acquiring technical knowledge is a fascinating one.]

THE WHEATSTONE AUTOMATIC.

In the Wheatstone system what is the function of the perforated paper?

Are the currents used in this system of one polarity or both polarities?

How are the lengths of the received characters governed?

Where are the two needles located with reference to the perforated tape?

How does the tape operate the pole changer?

If there are no perforations in the tape, does the pole changer operate?

What kind of a relay is used at the receiving station?

What governs the operation of the relay armature?

What instrument does the polar relay at the receiving end of the line control?

What causes the limitation of speed in the Wheatstone system?

What advantage is there in the comparatively slow speed of the Wheatstone system?

In what way does the operation of the Wheatstone system resemble hand (Morse) operation?

In sending a dot on a polar duplex or the polar side of a quadruplex, how many motions are made and how often is the polarity of the current changed?

In closing the key at the sending station, what action takes place in the distant polarized relay, and when the key is opened what is the effect upon the relay?

How many main pieces of apparatus does the Wheatstone system consist of?

What is the perforator?

Describe the construction of the perforator.

Why is the paper tape dipped in oil?

How is a dot represented by holes punched in the tape?

What does one perforation represent (see Fig. 52)?

How is a dash represented?

What is the purpose of the star-wheel in the perforator?

How is the punching done?

What punching-speed can an expert attain?

Why cannot a higher speed be made?

What is the character used to represent the letter L, and why was it necessary to change the Morse character for L?

Message Clip Stand.

The office of the engineer of equipment of the Western Union Telegraph Company, New York, has designed a message clip stand to hold received messages until they are picked up by the check clerk.

The clip holds the messages by means of its own weight, which insures easy ingress and egress, and at the same time prevents their blowing off the table.

The stand is constructed with a cast-iron base, into which is fitted a curved upright pipe, with a gravity clip at the top, and the whole is finished in black enamel.

The stand is intended to be placed on the table directly back of the typewriter drop on receiving positions only. This brings the clip in such a position that a message can be inserted directly into the clip with the same movement that draws it from the typewriter carrier.

It is equally convenient for pen receiving and affords a minimum of reach.

Earth Antennæ for Wireless Telegraphy.—Count Georg von Arco, in the course of a lecture delivered recently in Berlin, Germany, discussed the subject of wireless telegraphy. He stated that the question had for a long time remained undecided whether the distant effects were caused through the air or the earth, or through both media simultaneously. During the course of years experts became more of the opinion that the earth was largely concerned with the transmission. In order to obtain information on the matter, systematic experiments had been made during the past two years by Dr. Kiebitz, on behalf of the German postal authorities. It was found in this connection that electrical energy was transmitted for considerable distances through the earth, and that in the case of great distances sufficient energy could even be taken from the earth alone for the purpose of reception. Stimulated by these results, the Gesellschaft für Drahtlose Telegraphie had made numerous experiments in the past year, and had applied for various improvements in patents. The effects of the earth antennæ were sharply directed, and the antennæ in many respects showed advantages over air antennæ. In particular it was possible considerably to increase the security against interruptions by atmospheric discharges and by stations causing disturbances.—London *Electrical Review.*

The Serial Building Loan & Savings Institution, New York, has issued, in pamphlet form, the annual address of President A. G. Saylor. The address gives much interesting information regarding this worthy institution and incidentally dwells upon the importance of saving while young.

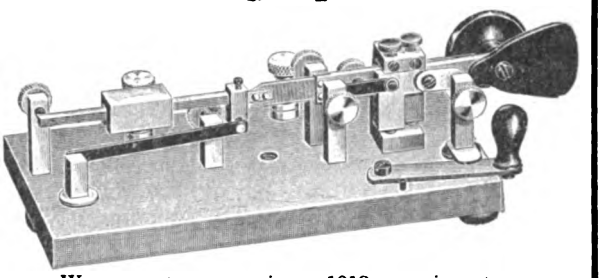
New Book on Telephony.

A new book entitled "Modern American Telephony in All Its Branches," edited by Arthur Bessey Smith, is now ready for delivery. It contains over 800 pages and nearly 600 illustrations, and is the most complete and up-to-date work on the subject. The price is $2.00 per copy. Address TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

The Mecograph Premier



We are not announcing a 1912 experiment.

Our offering for 1912 is the MECOGRAPH PREMIER.

There is none better than the best—and the best, at any price, is the MECOGRAPH PREMIER.

After six months of the most general service, the MECOGRAPH PREMIER has more than confirmed every hope and claim, and more than satisfied all buyers.

Price 8.00. Positively Guaranteed
Carrying Case, $1.25 extra

Modern American Telephony

In All Its Branches

THIS book, edited by Arthur Bessey Smith, E. E., assisted by a large corps of telephone experts, is just off the press. It is new, up to date, and covers every phase of the theory and practice of telephony, and will be found invaluable by engineers and students.

The book is pocket size, bound in black seal leather and contains about 800 pages and upward of 400 engravings and diagrams. The subject matter is treated in clear and simple style, and everyday problems are dealt with in a practical manner which will recommend this handbook to all members of the telephone profession.

Reminiscences of Charles Minot.

BY JOHN C. HARING, PIERMONT, N. Y.

The reminiscences published in your issue of December 16, 1911, of Charles Minot, to whose memory a monument is to be erected at Harriman (formerly Turner), N. Y., reminds me very vividly of the time when he was general superintendent of and I was a conductor on the Erie Railroad. When he desired to ride on the Eastern division and branches our train dispatcher, Mr. Henderson, or Wandel, would call me to run the train "wildcat" to any points Mr. Minot wished to go on an inspection trip.

Mr. Minot very much enjoyed a good story or a joke along with business. On one occasion he was at Port Jervis and asked me when I was going east. I told him I had orders to go as soon as we could make up the train, which would be an extra freight. My regular passenger run was on alternate days, and, whenever freight was running heavily, we would use the passenger engines for extra runs to Suffern and return. He said: "All right, I'll go with you." A short time before, orders had been issued to remove all seat cushions from the cabooses, which order had not been carried out in this particular caboose, but I had time to tell the crew that Mr. Minot would ride down with us. When he got in the caboose there were no cushions in sight. Mr. Minot was quite a portly man, and, while he was lying on the board locker, his stomach performed gymnastics. He stood it pretty well until we reached Turners. Before he got off, he complained about the caboose riding so hard and told me to ask Charley Cooper at Port Jervis to take it in shop for new springs, as it would wear out the conductors faster than he could provide them.

Mr. G. M. Huntington in his reminiscences states that Mr. Minot was not as particular as he should have been to obey his own rules. As an instance of this, when he found the caboose rode too hard, he said the brake had been used too much, which had flattened the wheels, and he said he thought he would take the brakes off entirely. When I replied that that would conflict with his instruction book, which stated plainly that the rear car on any train must be a good brake car, he said, "Well, I can easily change that!"

Mr. Minot had a way of his own to test his men to see if they knew their business, and had studied the instruction book, but he was universally liked.

Announcement.

Otto and Hugo Hoenack, sons of the late Paul Hoenack, with whom for the past twenty years they have been associated in the manufacture of electrical experimental and working apparatus, including telegraphy in all its branches, cable, multiplex, printing and automatic, also in telephony and general high class experimental work, wish to announce that the business will be carried on with the same high degree of expert mechanical efficiency as heretofore, under the name of Paul Hoenack, at 108 Park Row, New York.

T. M. B. A. Annual Report.—The published proceedings of the forty-fifth annual meeting of the Telegraphers' Mutual Benefit Association held in New York, November 15, 1911, are being distributed among the members. They are gotten up in the usual comprehensive form, and tables show the growth of the association by years since its organization. Mr. M. J. O'Leary, 195 Broadway, New York, secretary of the association, will be glad to furnish copies to anyone contemplating applying for membership.

Association of Broker Telegraphers.—The annual report of secretary Chester L. Hall of the Association of Broker Telegraphers of New York has been issued in pamphlet form. The primary object of this association is to secure for its members satisfactory positions at satisfactory remuneration, and, while the association confines its work principally to New York City, it is willing to help its members in other cities as far as it can.

Things to know about Telephone Systems.—The Kellogg Switchboard and Supply Company, Chicago, has issued a pamphlet entitled "Things Telephone Users Should Know About Telephone Systems and Service." The information it contains is well worth careful consideration.

Calendars for 1912.

We have received calendars for 1912 from Messrs. J. H. Bunnell & Co., The James Kempster Printing Company and Serial Building Loan & Savings Institution, New York.

A Fatal Cigarette.—Albert G. Bouton, a lineman, while working on top of a telegraph pole in South Norwalk, Conn., January 5, attempted to roll a cigarette. He lost his balance and fell to the ground and was killed.

Valuable Books.

Practical Telephone Handbook and Guide to Telephonic Exchange. By T. S. Baldwin.

This book contains chapters on the use of the telephone, line construction, line materials, locating and correction of faults in lines and instruments, besides much other information of value to promoters, builders and managers of rural telephone lines. It is written in popular language and covers the field of telephony very thoroughly. The book is well illustrated. Price $1.00 per copy.

Operators' Wireless Telegraph and Telephone Hand Book. By Victor H. Laughter.

A complete treatise on the construction and operation of the wireless telegraph and telephone, including the rules of naval stations, codes, abbreviations, etc. The principal systems of wireless telegraphy are described and altogether this book will be found an excellent aid in the study of the art and practice of wireless telegraphy and telephony. It is profusely illustrated with views and diagrams of instruments, etc. Price $1.00 per copy. For sale by TELEGRAPH AND TELEPHONE AGE, New York.

Signal Corps Men Elect Officers.—Gen'l A. W. Greely, camp United States War Veterans, held their annual election of officers at Chicago, December 28, and elected these officers: Geo. Lee, commander; Richard S. Gill, senior vice commander; Danl. F. Delahunt, junior vice-commander; Jos. A. Beckemeyer, adjutant; John W. Konigsmark, quartermaster; Capt. J. W. McConnell, trustee. Greely Camp is composed entirely of signal corps men who served during the Spanish-American war, the membership being scattered throughout the United States.

Annual Meeting of Serial Building Loan and Savings Institution.

At the recent annual meeting of the Serial Building Loan and Savings Institution held at 195 Broadway, New York, the following officers were elected: A. G. Saylor, president; James R. Beard, vice-president; E. F. Howell, secretary.

Directors: A. G. Saylor, Thos. M. Brennan, T. E. Fleming, G. W. Blanchard, M. S. Cohen, H. A. Konninger, W. B. Dunn, James R. Beard, M. W. Rayens, W. J. Quinn, M. J. O'Leary, E. E. Brannin, C. A. Kilfoyle, J. T. Laidlaw; attorney, John T. Mulhall.

Advisory Committee: Chas. P. Bruch, Thos. W. Carroll, E. S. Butterfield, John A. Hill, W. H. Baker, Edwd. Reynolds, E. M. Mulford, A. C. Terry.

The report for the six months ending December 31, 1911, shows:

ASSETS.

Cash	$19,256.01
Mortgages	516,912.23
Loans on shares	5,688.00
Real estate	14,733.30
Land contracts	5,894.61

Due on loans	3,000.00
Surplus	43,166.92
	$564,118.61

New Western Union Office at Memphis, Tenn.

The Western Union Telegraph Company has moved into new quarters in Memphis, Tenn., and now has one of the best equipped and most thoroughly up-to-date telegraph offices in the country. The entire office is fitted up in oak with furniture to match, and brass pneumatic tubes run to the operating department, which is located on the fourth floor. The bookkeeping, delivery and telephone departments are divided off by a frosted glass partition so that the public only see the desks of officers. All customers' writing desks in the lobby are covered by heavy plate glass. The employes have also been provided with suitable rest and locker rooms, and every attention has been given to their comfort and convenience. L. E. Rudd is manager, J. C. Young, cashier; J. E. Lively, chief operator; W. D. Pard, wire chief; R. E. Griffey, repeater chief; C. R. Vestal, night chief operator; L. C. Howard, all-night chief operator, and E. A. Shaw, day traffic chief.

New York Telegraphers' Aid Society.

The New York Telegraphers' Aid Society's financial statement for the quarter ended December 6, 1911, shows:

Balance on hand September 6, 1911		$24,493.71
Receipts		1,685.50
Total		$26,179.21
Disbursements—		
Sick Benefits	$757.90	
Death "	300.00	
Expenses	164.00	
		1,221.90
Balance on hand December 6, 1911		24,957.31
Total		$26,179.21

RELIEF FUND.

Balance on hand September 6, 1911	$5,508.16
Receipts	496.39
Total	$6,004.55
Disbursements	152.90
Balance on hand December 6, 1911	5,851.65
Total	$6,004.55

Philadelphia Electrical Aid Society.

The annual meeting of the Electrical Aid Society of Philadelphia was held January 9 and the officers elected for 1912 are: President, Wm. R. Harmstad; vice-president, A. G. Strickland; recording secretary, W. E. Van Arsdall; financial secretary, R. C. Murray; treasurer, J. H. Wilson. Executive committee: F. E. Maize, A. S. Weir, Miss Mary McFadden, Mrs. N. H. Maloney. Trustees: George J. Wells, R. H. Conway, Merritt H. Redding.

Amendments were passed increasing the salaries of the recording and financial secretaries and the cashier. At the close of the business a banquet was held, after which dancing was indulged in.

LETTERS FROM OUR AGENTS.

LOS ANGELES WESTERN UNION.

On December 22 the Los Angeles-San Francisco printers handled 1,749 regular messages including 550 night letters on one wire working duplex in fifteen and one-half working hours. There were also eighty-two service messages handled. The length of this circuit is about 600 miles. Mr. A. L. Fish is printer chief days, and C. J. Covher nights. The chief operators of the Los Angeles office are A. C. Parsons, days; C. C. Hawcroft, early night, and D. F. Ingold, late night.

Digitized by Google

NEW YORK WESTERN UNION.

Mrs. Marietta F. Adams, aged 68 years, an operator in this office for the past 35 years, was found dead at her home in Brooklyn, N. Y., on January 2.

Maurice J. Coughlin, formerly of this office, died in New York January 11.

Mr. James V. Riddick will sail for his former home, Port-Arlington, Ireland, on January 17, on the steamer *Baltic,* and expects to be absent about one month.

Mr. W. L. Ives has been absent for several days on account of sickness. His many friends will be pleased to hear that he is on the road to recovery, and hopes to soon be able to resume duty.

OKLAHOMA CITY WESTERN UNION.

Improvements are being made to the office and equipment. Arrangements for the installation of a Barclay printing system have also been made, as well as plans for an increased delivery system, and a more efficient check service.

A new Athearn multiplex system is also being installed. We expect to have all trunks equipped with these sets at an early date. The work of installation is in the hands of Mr. L. J. Tucker, the day wire chief, who is performing the work admirably.

Several changes have been made among the chiefs. Mr. L. J. Tucker has been appointed day wire chief, vice Mr. H. K. Pottenger, who has been transferred to the night board and loops, vice Mr. J. F. Slack, appointed to the position of late night chief. Mr. T. G. Meader has been made assistant traffic chief days.

Traffic chief G. C. Moeser was the recipient of a handsome gold watch and fob at Christmas from the office force. In a neat speech he manifested his appreciation and thanked the force, wishing us all a Merry Christmas and a Happy New Year.

SAN FRANCISCO WESTERN UNION.

This company has opened a training school for the benefit of its younger employes under the direction of competent instructors. It is equipped with up-to-date telegraph apparatus and is arranged so as to receive students in any stage of advancement. Main line practice is afforded. The school is open all day and during the early evening. At present only telegraphy is taught, but the experiment has been so successful that the company is considering the advisability of adding instructions in telegraph accounting so that the graduates will be competent to take charge of a telegraph office. There are now sixty to seventy pupils.

Messrs. M. B. Brown and John Egan, who have been confined at home for a long time with sickness, were the recipients of Christmas and New Year's greetings from their many friends in the telegraph service. Mr. Brown has served the Western Union for the past forty-five years, and was at one time manager for this company at Des Moines, Ia., and Salt Lake City, Utah. He has been located at San Francisco for the past ten years. Mr. Egan has been a telegrapher for fifty years and has served the Western Union at New York and other important points. He came to the coast in the golden days, when Virginia City, Nev., was one of the busiest offices. After spending some time in the mining camps of Nevada, he found his way to Sacramento, at which point he was chief operator for a number of years. He has been located at San Francisco for the past fifteen years.

WINNEMUCCA, NEV., WESTERN UNION.

One of the finest and thoroughly equipped repeater offices in the country has been established at this point. The Western Union overland circuits following the Western Pacific and the Southern Pacific converge at this place, which is just half way between San Francisco and Salt Lake, and many important circuits are repeatered here, including the Southern Pacific multiplex circuits. The repeaters are handled by Messrs. J. H. Hadley, J. C. Tucker and H. B. Witter. Mr. S. J. Mercer is the manager, and while Winnemucca is a small place, big things can happen. Mr. Mercer within a year has secured forty-one clock subscribers and now has one clock subscriber for every forty-five inhabitants.

Among sound and reliable insurance organizations the Telegraphers' Mutual Benefit Association of 195 Broadway, New York, occupies a foremost place. Organized in 1867, it has paid to beneficiaries of deceased members $1,650,000. Reserve Fund, $328,000, the largest Reserve in proportion to liabilities that is held by any similar Association. All persons engaged in Telegraph or Telephone service between the ages of 18 and 45 are eligible for membership, no restrictions after admission as to change of occupation or residence. The lowest possible cost consistent with security offered. Write for blanks and further information.

TRANSMITTING MACHINES

I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to

James Uncles, NORTH ADAMS Massachusetts

The great telegraphic song hit,
"SEND ME A NIGHT LETTER, DEARIE."
Good, catchy music; beautiful title design magnificently printed in colors. Title contains night letter. Sung all over New York, 17c. by mail. All popular music sent by mail.
B. L. BRANNAN,
195 B'way, N. Y.

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

New Wrinkles in the Construction of Apparatus.

An old timer in point of service and well informed concerning the operation of telegraph apparatus, after admiring neatness of construction and admitting the acquisition of a number of new appliances remarked: "After all there don't seem to have been any, or, at least, very many changes in the construction of the principal apparatus used. We still have the same old relays, condensers, rheostats and many other devices that look about the same today as they did years ago."

In a sense his remark is true; they do "look" somewhat the same, but in some respects they are not the same.

His remark recalls the substance of a number of inquiries from correspondents showing that there is a desire to know more about the inner construction of apparatus than text-books usually give. It is the lack of such information that creates the erroneous impression that electrical engineering is not progressing as rapidly as it might.

It would probably be better for all concerned if quadruplex attendants knew the "true inwardness" of their instruments better, and as there has always existed considerable curiosity along that line on their part it seems proper that they should have the desired information. It is certainly not wilfully withheld.

For illustration let us take one of the old pieces of apparatus that "looks the same," say, a quadruplex proportion box, otherwise known as the "leak" and "added resistance" box. They resemble the earlier devices from the outside and have the same number of ohms resistance, in each division, but there the resemblance ends. The material and inner construction are entirely different. The coils of the old type usually consisted of silk or cotton-covered german silver or or other high resistance wire and frequently became defective through overheating which destroyed the insulation.

The coils in the new type contain no such covering. They consist of enameled wire wound around a porcelain tube with a thicker coat of hard enamel covering the entire coil. Wires so treated are practically indestructible when used in the manner for which they are intended. There are three of these tubes in the modern box, each of which possesses 900 ohms. One of them is tapped at 600 ohms for one shunt, another at 100 ohms for the second shunt, while the third is connected in series with one of the other two to provide the "added resistance."

Nor is this the only example indicating the discontinuance of the use of fabric insulation for coil windings. Nearly all our modern rheostats, such as the radial arm, the combination leak box, the line resistance, condenser retardation coils, as well as several others, contain coils without even a suspicion of silk, cotton or other inflammable covering for the wire. All these consist of wire coated with a hard enamel. Industrial companies are now making resistance units of nearly all values required in telegraph and telephone service so that it is hardly necessary or even economical to the operating companies to wind them.

It is probably safe to say that the day is not far distant when all our relays will be enamel insulated. In fact we have some now. The little 1-ohm signal relay seen on the top of multiplex tables which controls the frosted pear-shaped lamp is one of them, and there are others on trial, all of which have proved satisfactory. There seems to be no physical reason why they should not come into general use, as wire with enamel covering has another advantage aside from that of insulation. In the first place the enamel occupies less space than do cotton or silk, as it is very thin, hence a greater length of wire could be wound on the spool within a given space. Consequently a larger gauge wire would provide the same number of convolutions on the spool, and have a lower total resistance.

Digitized by Google

Another old apparatus that "looks just the same," is the condenser, but the new type is much superior in many ways. In the old type the tinfoil and dielectric consisted of a great number of square sheets with the edges of the different groups joined together in order to get the superficial area equivalent of one large sheet. In the new type each unit consists of only one long sheet of tinfoil and one of paraffine paper rolled together. This method not only eliminates the necessity of joining the edges, but requires less space.

A glance at the combination condenser used in connection with multiplex apparatus will show that the box is several inches shorter than the old type box, yet it contains an additional 1 m. f. condenser for the "spark."

Not only that but the group is made up of a number of standard unit condensers, seven of 1 m. f. each, and two of ⅞ m. f. each, contained in separate little japanned tin boxes not more than 1½ inches square by about 4 inches long, any one of which may be detached or replaced without disturbing the others.

As in the case of rheostats it is no longer necessary to keep in stock so great a variety of condensers in order to provide different capacities. Such requirements are now met by combining the different units as the occasion demands. As previously stated, being in roll-sheet form they occupy comparatively little space, while the detachable boxes are adaptable to almost any unoccupied space on or under the table where they may be required.

Again we shall soon see fewer resistance lamps than now. Enameled units of various resistance values will supersede the carbon filament lamp in many cases not because they are necessarily more efficient or cheaper, but because they are more durable, just as efficient, and easier handled.

Students should endeavor to look deeper in the details of construction. It is not only an interesting study, but the knowledge thus gained stimulates inventive tendencies. One cannot well improve an apparatus until he knows its construction and is thus afforded an opportunity to compare existing material and methods with something he may deem better. All of the improved apparatus herein mentioned has been brought about through the perception of some close observer.

Recent Telegraph and Telephone Patents.

Telegraph and Telephone Stock Quotations.

Following are the closing quotations of telegraph and telephone stocks on the New York Stock Exchange January 26:

Amer. Telep. and Teleg. Co.	140¼
Mackay Companies	75
" " pfd.	70
Western Union Tel. Co.	83¼

Personal.

Mr. Roy W. Thomas, general news manager of the United Press, New York, is on a business trip to the Pacific Coast.

Mr. C. H. Shedd, of the telegraph and telephone department of the National Packing Company, Chicago, was a recent New York visitor.

Mr. F. L. Hutchinson has been appointed secretary of the American Institute of Electrical Engineers, New York. Mr. Hutchinson has been acting secretary since the resignation of Mr. Ralph W. Pope on August 1, 1911.

Mr. Frank C. Mason, of Washington Mills, N. Y., an old-time telegrapher and former superintendent of telegraphs of the police department, Brooklyn, N. Y., has been elected an honorary member of the New England Historical Society.

Mr. F. Douglas Watson, former provincial superintendent for the National Telephone Company in Scotland, who was recently appointed general manager and secretary of the Société Anonyme Ottomane des Téléphones de Constantinople (Constantinople Telephone Company), has taken up his duties in Constantinople.

Mr. H. A. Reed, president of the Bishop Gutta-Percha Company, New York, a forty-niner of the telegraph, and author of the story of Professor Morse, which appeared in the January 16 issue of this paper, has gone to Florida where he will spend the next few weeks. Although Mr. Reed is 83 years of age he is enjoying the best of health.

Mr. P. V. DeGraw, fourth assistant postmaster-general, Washington, D. C., has submitted to postmaster-general Hitchcock, his annual report for the fiscal year ended June 30, 1911. It is an interesting document and shows progress in this branch of the service. Mr. DeGraw is an old-time telegrapher and was a member of the celebrated staff of operators on the original Associated Press leased wire between New York and Washington.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. E. B. Pillsbury, general superintendent, New York, sailed on Saturday, January 27, for Panama and the West Indies on a vacation trip of three weeks.

Mr. G. H. Usher, general superintendent of the Southern Division, Atlanta, Ga., was an executive office visitor in New York on January 23 and 24.

Mr. W. J. Capen, general superintendent of plant, will be in Texas for several weeks to come on business connected with construction work in that State.

A daughter was born on January 17 to Mr. and Mrs. J. F. Skirrow. Mr. Skirrow is associate electrical engineer of the company.

Mr. E. W. Collins, superintendent, Cleveland, Ohio, was a recent New York visitor.

Mr. W. B. Dunn, assistant secretary of the company, and a director of the Serial Building Loan and Savings Institution, New York, is starting a vigorous campaign to increase the membership of the Institution among executive office employes.

Mr. C. Troeller, Jr., has been appointed manager of the Atlantic City, N. J., office of this company, vice W. M. Phillips resigned.

Mr. P. Chamberlain, manager of the Mackay Telegraph and Cable Company, Waco, Tex., has been appointed supervisor, and has been succeeded as manager by Mr. S. S. Lacey, formerly night chief operator at Dallas, Tex.

New quarters have been leased for this company's office in Indianapolis, Ind. Mr. G. F. Fuller is the manager.

The San Antonio, Tex., office of the Mackay Telegraph and Cable Company opened for business on February 1. Mr. J. B. Sampley, manager of the Austin, Tex., office has been appointed manager at San Antonio.

Postal Tariff Book for 1912.—The Postal Telegraph-Cable Company has issued its tariff book for 1912, revised and brought up to date. Complete instructions are given with reference to cable messages together with rates and rules governing this service. The money transfer service is the subject of general instructions in a special section of the book; as is also the rules for the government of the receiving department. At the back of the book are given maps of the Commercial Cable Company's systems as well as those of affiliated companies. This book was compiled and issued under the supervision of Mr. Isaac Smith, superintendent of tariffs, New York, and bears evidence of intelligent and painstaking work.

Prominent Telegraphers at Ohio Society Banquet.

The thirtieth annual banquet of the Ohio Society of New York was held at the Waldorf-Astoria, Saturday evening, January 27, President Taft being the guest of honor. The occasion was made memorable by the presence of many well-known former and active telegraph men, including Mr. Andrew Carnegie and Mr. James Bertram, his secretary, Mr. Theo. N. Vail, president American Telephone & Telegraph Company and the Western Union Telegraph Company, New York. Mr. Newcomb Carlton, vice-president Western Union Telegraph Company, New York; Mr. E. J. Nally, vice-president and general manager Postal Telegraph-Cable Company, New York; Mr. C. C. Adams, and Mr. C. P. Bruch, second and third vice-presidents, respectively, Postal Telegraph-Cable Company, New York; Mr. F. H. Bethell, vice-president New York Telephone Company, New York; Mr. W. C. Brown, president New York Central Lines, New York; Mr. D. H. Bates, secretary Society of the United States Military Telegraph Corps, New York; Mr. Frank Munsey and Mr. Frank N. Dowler, New York.

Messrs. Theo. N. Vail, C. P. Bruch, D. H. Bates, F. Munsey and F. N. Dowler, are members of the Society. Mr. Bates was selected to escort Mr. Carnegie to the guests' table. Postmaster-general Frank Hitchcock was also present.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

President Theo. N. Vail states that there will be no increase in the dividend rate at the March meeting of the Board of Directors of this company as was reported recently in the daily newspapers.

Mr. Belvidere Brooks, general manager; Mr. A. G. Saylor, general superintendent, New York, and Mr. W. C. Merly, secretary to Mr. Brooks, New York, visited Philadelphia, Baltimore and Washington recently on company business.

Mr. W. E. Athearn, engineer of equipment New York, was a recent visitor at Pittsburgh, Pa., and Wheeling, W. Va., on business connected with the service.

Mr. A. C. Terry, district commercial superintendent at Pittsburgh, Pa., was a recent New York visitor.

Mr. F. A. Aspinwall has been appointed manager of the office at 270 West Twenty-third St., New York, vice Miss M. L. Barry transferred to the Knickerbocker Hotel.

Mr. M. S. Snedeker, superintendent of the Western Union building in Chicago, has resigned and is succeeded by W. I. Lake.

Mr. L. K. McNees, formerly of Gulfport, Miss., has been appointed manager of the Jackson, Miss., office of this company.

Mr. H. R. Stallings, formerly manager of the Sherman, Tex., office, has been appointed traveling auditor for the company.

Mr. S. P. Jones, manager of the Houston, Tex., office of this company, has been transferred to the managership of the El Paso, Tex., office and Mr. R. D. Gould, manager at El Paso, takes Mr. Jone's place at Houston. These transfers were made for account of the ill-health of the wives of these two gentlemen.

Mr. J. S. Calvert, district superintendent, Rich-

Digitized by Google

mond, Va., announces the following recent appointments of managers in his district: Miss Ruby Bowden at Clio, S. C., vice F. B. Markey, who has left the service; J. B. Pope, at Rockingham, N. C., vice P. C. Bowling, left the service; W. T. Tignor at Wilson, N. C., vice W. V. Emory who enters the operating department at Charlotte, N. C. (Mr. Tignor was transferred to Wilson from the operating department at Richmond, Va.); Mrs. Annie E. Parks, at Barnwell, S. C., vice C. J. McNab who has left the service, and E. M. Phillips, at Weldon, N. C., vice W. G. Fowlkes.

Mrs. M. I. Ufford, chief operator at New Haven, Conn., has retired from active telegraphic duties after a service of fourteen years with this company. She is a sister of Mr. S. E. Lonergan, manager of the New Haven office. Mr. John George, night chief operator, has been promoted to be chief operator, vice Mrs. Ufford.

The regular monthly meeting of Group 2 of the Commercial Association of the Western Union Telegraph Company, New York, was held at 195 Broadway, January 25. In addition to the local managers, the receiving and delivery clerks were present.

This company has taken a 20-year lease for quarters in the new "Woodmen of the World" building in Omaha, Neb., and will fit up fine offices. The operating department and district offices will be located on the fifteenth and sixteenth floors, the commercial office on the ground floor.

Electrical Class in Jacksonville.—A student class has been started in the Western Union office at Jacksonville, Fla., Mr. Albert J. Dillon being the instructor. The class is in charge of manager W. R. Edmondson and acting chief operator R. L. Branton.

The Morse Electric Club Dinner.—The annual dinner of the Morse Electric Club, which will be held at the Hotel Savoy, Fifth Avenue and Fifty-ninth Street, New York, Saturday evening, February 17, will be attended by several prominent men as guests. The entertainment committee is making arrangements for a suitable programme. Mr. R. J. Murphy, 195 Broadway, New York, is treasurer to whom applications for tickets should be made not later than February 14.

The New Western Union Building in New York.

Rapid progress is being made in the construction of the new building in New York to be occupied jointly by the Western Union Telegraph Company and the New York Telephone Company. This building is located on Walker and Lispenard streets, and was described in our issues for February 16, September 16 and October 16, 1911, illustrations being shown in the first named issue. The foundations are now under way and it is expected that the building will be so far advanced by January 1, 1913, that the installation of the telegraph and telephone equipment will be started at that time. The building will be ready for occupancy about the middle or latter part of the summer. The engineering forces of both companies are busy drawing the plans for the new offices and equipment.

The Cable.

Mr. Basil C. Combe, captain of the Commercial Pacific Cable Company's steamer "Restorer," of Vancouver, B. C., was a recent New York executive-office visitor on company business.

The Mexican Telegraph Company and Central and South American Telegraph Company have issued a folder giving a map of their systems. On the front page is a colored picture of the flags of all the countries touched by the lines of these companies.

Extension of Half-Rate Cable Service by Commercial Cable Company.

The Commercial Cable Company has announced that it will transmit, subject to the conditions of acceptance, messages written in plain language at a reduction of fifty per cent from the charges for an ordinary message to Great Britain and Ireland, France, Germany, Portugal, India and Burmah, Aden, Algeria, Ascension, Bathurst, British North Borneo, Ceylon, Cocos Island, Cyprus, East Africa and Uganda, Gold Coast, Labuan, Mauritius, Northern Nigeria, Southern Nigeria, Perim, Southern Rhodesia, Rodriguez St. Helena, Sierra Leone, Somaliland, South African Union, Straits Settlements and Malay States, Tunis and Zanzibar.

The conditions are the same as those published on page 37 of our issue for January 16, with the exception of two changes which read as follows:

The text must be written entirely in the plain language of the country from which the message is sent, or entirely in the plain language of the country to which the message is addressed, or entirely in the French plain language. Other languages or mixtures of any languages are not admitted.

A reply to a deferred plain language message may be prepaid but the instruction must be expressed in the terms of full rates. For example: If the sender of a deferred message wishes to prepay a deferred reply of twenty words the instruction to be written before the name and address should be —R P 10—.

New City Electrical Positions.—The Board of Estimate of New York City has made an allowance of $200,000 for the establishment of a fire prevention bureau. The bureau will have an assistant electrical engineer at an annual salary of $3,000 and two electrical inspectors at a salary of $1,800 each.

A Future Investigation.—The British postmaster general has promised to appoint a committee of inquiry in 1913 to investigate the grievances of the telegraphers in the postal service in that country.

Digitized by Google

The Telephone.

Mr. H. B. Thayer, president of the Western Electric Company and vice-president of the American Telephone & Telegraph Company, New York, sailed for Europe on January 24 and will be absent about six weeks.

Telephone Between Paris and Madrid.—On January 1, telephone service between Paris, France, and Madrid, Spain, was inaugurated. The distance between the two cities is about 1,000 miles.

All-Night Shopping by Telephone.—A number of large firms in London have made arrangements for receiving orders for goods by telephone at all hours of the night, the articles required being dispatched by the first delivery in the morning.

Combined Telephone and Electric Light.—A patent has recently been granted on a combined desk telephone and lamp standard. The unique feature of the invention lies in the fact that the transmitter is located in the top of the electric light shade, the shade also serving to gather up the sound and concentrate it upon the transmitter.

Telephone Merger in Utah.—The Mountain States Telephone and Telegraph Company, with headquarters at Denver, Col., assumed active control of the Utah Telephone Company in Ogden, Utah, on January 1. The merger adds 1,000 subscribers to the Mountain States Company. The physical absorption of the independent plant at Salt Lake City has been deferred until June.

A Discovery by Mr. Marconi.—During some experiments in the desert in Tripoli, according to a despatch from Rome, Mr. William Marconi discovered that wireless messages could be sent with security over the desert without the usual masts. Instead of poles, wire is laid on the sand, in the direction in which the message is to be sent. The message is received without any interruption, exactly the same as though the usual system were employed. The sand, being a non-conductor, electric waves are not affected in any way.

Time Consumed in Answering Telephone Calls.—The average time consumed by telephone operators in answering calls in some of the larger exchanges in New York State is shown in a report of the Public Service Commission, second district. Rochester stands at the head of the list, with 3.4 seconds per call, then follow Jamestown, 3.6; Watertown, 3.7; Buffalo, 4.1; Troy, 5.2; Albany, 5.5, and New York, 6.6. The Inspectors who made the investigation report that they found the service to be much faster in cities than in small places, as a result of the public demand for speed where business is urgent. They also report that the tests in New York City were made in the holiday season and were taken at two central offices, against which complaints were made. They say that these tests show a slow service, and are probably unfavorable as compared with the general service throughout the city.

To Redeem Telephone Stocks.—The American Telephone & Telegraph Company, which in 1909 bought from the Western Union Telegraph Company some $16,000,000 of the stock of the New York Telephone Company, will come into the possession of the final $9,733,100 of its purchase after May 1. At the time of the purchase it was explained that $9,733,100 of the stock had been pledged in 1906 as collateral for $10,000,000 convertible 4 per cent. collateral bonds of the telegraph company, of which $8,000,000 are outstanding. These bonds, which are due in 1936, are redeemable May 1 at 105.

Highest Telephone Station in the World.—The highest telephone line in the world is said to be that to the summit of Monte Rosa, in Italy. The line connects with the observatory on the summit which has an altitude of 14,960 feet above sea level. The poles carrying the telephone line are set in the snow, largely on the surface of glaciers, and the construction involved the solving of many difficult and unusual problems. It is in operation but a short time each year, the poles being removed and stored for re-building the following year. In order that the shifting of the glaciers might not break the wires, the latter are not made fast to the insulators, but are strung through rings, thus allowing free play. The middle of each stretch of wire, between the poles, rests on the snow, while in the uppermost section of the line, between the Col du Lys and the summit, poles are dispensed with altogether, the wire being simply laid on the surface of the dry snow. In one of the lower sections of the line two valleys had to be crossed, each over 3,000 feet wide. In each case a single span of heavy steel wire was installed. The line was opened on September 8, 1909.

Radio-Telegraphy.

Wireless in Russia.—The Russian government has decided to establish wireless stations on the coasts of the White and the Kara seas.

Wireless Equipment for Yachts.—Mr. J. P. Morgan's yacht "Corsair" and Mr. G. W. Vanderbilt's yacht "Warrior" have been equipped with 3-kw. Marconi wireless outfits.

Compulsory Wireless in Uruguay.—The Uruguayan government has decreed that passenger vessels calling at ports in that country after May 1 will be required to be equipped with wireless telegraph outfits.

Marconi Dividend.—The Marconi Wireless Telegraph Company, London, England, will, on February 1, pay a dividend on the seven per cent cumulative participating preference shares for the six months ending December 31.

Modern Wireless.—Mr. W. E. Dixon Bennett read a paper entitled "Radiotelegraphy in Modern Practice," before the South African Institute of Electrical Engineers on December 21, 1911. It is historical as well as practical, and goes into the subject very fully. It is published in full and illustrated in the transactions of the institute.

Digitized by Google

Transatlantic Wireless Station for New York.—Mr. John Bottomley, vice-president and general manager of the Marconi Wireless Telegraph Company of America, New York, is authority for the statement that his company will erect in or near New York in the near future a high power wireless station for the purpose of handling transatlantic messages directly with Clifden, Ireland, or some other station in Great Britain.

Wireless Appointments.—Mr. A. H. Ginman, formerly manager of the Marconi wireless station at Siasconset, Mass., has been appointed the company's representative for the Pacific coast division with headquarters at San Francisco, Cal. Mr. Ginman has as his chief assistant Mr. J. D. Taylor, who was formerly in charge of the Marconi staion at South Wellfleet, Mass. Mr. J. C. Cowden, chief operator at Siasconset has been appointed manager of that station vice Mr. Ginman.

Extensive Wireless System for Navy.—It is proposed to ask Congress for an appropriation of $1,000,000 to establish an extensive wireless system for the purpose of keeping the Navy Department in touch with naval vessels in the Atlantic or the Pacific oceans. The plan is to have powerful wireless stations at San Francisco, Panama, Pearl Harbor, Hawaii, Guam, Samoa, and the Isle of Luzon. The towers, of a height approximating five hundred feet, will be used either in direct or relay communication with the wireless towers now being erected for the navy at Arlington, near Washington.

Wireless on the Pacific.—The Marconi Wireless Telegraph Company of America, New York, has closed contracts to equip with wireless outfits thirteen steamers including those of the Matson Navigation Company and the California Atlantic Steamship Company, with headquarters at San Francisco, Cal. The company has also opened a land station at San Francisco and will open two additional stations at San Diego, Cal., and Seattle, Wash. Each of the land stations will have an operative radius of 1,000 miles at least, and the ships will have the same radius of operation, each being equipped with a 3-kw. outfit. The first ship fitted held communication with San Francisco, 1,500 miles away. All of the steamers referred to are in the Pacific trade.

Wireless Ship Equipments.—According to the report of the navigation commissioner of the Department of Commerce and Labor, Washington, D. C., the wireless ship act has been applied to 188 ocean passenger steamers leaving American ports, and 142 other vessels in this country have voluntarily equipped with wireless, while the total number of merchant vessels in the world thus equipped is 1,013. The act has been generally commended and steamship and wireless companies have willingly co-operated in its enforcement. Certificates of skill have been issued to 507 wireless operators and examinations will be held throughout the current year.

Investigation of Amateur Wireless Interference.—An investigation of the extent of interference by amateur wireless-telegraph operators in the transmission of legitimate messages between ship and shore stations has been undertaken by the United States Navy Department. The immediate cause of the investigation was a delay of more than one hour in the transmission of messages of distress from the torpedo-boat destroyer "Terry" recently. During this delay the wireless-telegraph apparatus on the vessel was disabled and the exact position of the ship in distress could not be ascertained. It is estimated that at least 500 stations are in use and owned by amateur operators in the neighborhood of New York.

Wireless Patents.

Proceedings at law have been commenced in New Zealand by Marconi's Wireless Telegraph Company, Ltd., against Huddart Parker, Ltd., says *The Marconigraph,* for infringement of the company's patents by the use of the Telefunken system of wireless telegraphy on board some of the latter company's ships plying between Australia and New Zealand. Similar proceedings have also been started in Australia against the same firm and the Australasian Wireless Company, who supplied the plant.

The Helsby Wireless Telegraph Company, Ltd., having applied for a license to work under the extended patent granted to Sir Oliver Lodge, and now the property of the Marconi Company, the Board of Trade appointed Sir Cornelius Dalton, late Comtroller-General of Patents, as arbitrator. The hearing commenced on December 11 and is still proceeding.

Messrs. Siemens Brothers & Co., Ltd., the assignees in England of the Telefunken system of wireless telegraphy, have also applied for a license to work under this patent, and are assisting the Helsby Company in the arbitration proceedings. It is contended on behalf of the applicants that they cannot work any system of wireless telegraphy without a license under the patent in question.

The Wireless Telegraph Situation.

Meetings of local stockholders of the United Wireless Telegraph Company have been held in various cities, notably New York, Philadelphia, and Cincinnati, for the purpose of devising ways and means to reorganize the company and protect, as far as possible, the interests of the many stockholders in the concern. Since the company went into the hands of receivers last year little of a definite character has been learned of the true condition of affairs and in justice to the hundreds of innocent stockholders the receivers should make a statement showing the actual situation.

The business of the company has been conducted almost wholly for the purpose of selling stock and it is regrettable that so important a utility as wireless telegraph should be so debased and used for fraudulent purposes. It is

Digitized by Google

absurd to imagine that a company with $20,000,000 stock outstanding and assets of less than a quarter of million dollars can ever hope to pay dividends, and this great disproportion will have to be reduced before the company's affairs can be placed on a legitimate basis. The unsuspecting stockholders were decoyed into the snare, of course, by the glowing pictures presented to them of the great usefulness of the wireless telegraph to navigation, etc., etc., and the unlimited possibilities for the paying of large dividends. The part of the story about the utility of wireless is true, but that part of it in reference to dividends is fabulous, and it was this part of the game that was emphasized more particularly for the benefit of the unwary investor.

As a matter of fact the revenues of a wireless station very rarely more than offset the maintenance expenses, and unless conditions change and more compensation is exacted for this class of service the United Wireless Company will find it extremely difficult to pay dividends on $1,000,000 let alone the $20,000,000 now outstanding.

Canadian Notes.

Government Ownership of Canadian Telegraph and Telephone Lines.—Hon. Joseph Armstrong, member of the Canadian Parliament, Ottawa, Ont., has introduced a resolution having in view the nationalization of the telegraph and telephone systems in Canada, and to operate them as a branch of the Post Office department.

Train Dispatching by Telephone.—Mr. W. J. Camp, assistant manager and electrical engineer of Canadian Pacific Railway Telegraphs, Montreal, Que., made an address on the subject of train dispatching by telephone, at a recent noonday dinner in that city of the Electrical Association of the province of Quebec. The Canadian Pacific was among the earliest roads, he stated, to recognize the advantages of telephone dispatching over the telegraph and now has nearly 4,000 miles of track controlled by telephone.

The Canadian Telegraph Investigation.

Another hearing in the investigation into the the operation of telegraph companies in Canada before the Board of Railway Commissioners was held in Ottawa, Ont., from January 8 to January 12 inclusive. Evidence regarding the Great Northwestern Telegraph Company was given by Mr. G. D. Perry, the company's general manager, and the investigation so far as that company is concerned is practically completed. The Board then proceeded with the investigation of the Canadian Pacific Railway Company's Telegraphs, evidence being given by Mr. W. J. Moule, assistant auditor, W. J. Camp, assistant manager of telegraph and Messrs C. H. Bristol, and E. P. Griffith from the United States. After spending four days in the examination regarding the Canadian Pacific Railway Company's Telegraph, the case was adjourned for further statements to be filed and will probably come up again in the course of two or three months.

Obituary.

Edoth Willis Humphrey, aged 51 years, president of the Northern Commercial Telegraph Company, of Montreal, Que., died in Brooklyn, N. Y., on January 14.

Frank P. Wyne, aged 55 years, a former telegrapher and a member of the Old Time Telegraphers' and Historical Association, died in Peoria, Ill., January 3.

Dr. John C. Graham, formerly a well-known telegrapher identified with the Western Union service in Cleveland in the early seventies, died at La Porte, Iowa, last month. He had been a prominent member of the medical profession of that State for the past thirty years.

Daniel B. McCoy, a member of the United States Military Telegraph Corps, died at Bogota, N. J., January 21. Deceased was formerly assistant general manager of the New York Central & Hudson River Railroad Company. He was an Old-Time Telegrapher and a well-known railroad official and had recently retired from active service.

E. N. Dennis, aged 53 years, night wire chief of the Western Union, Richmond, Va., office, died while at work on January 15. He was on extra duty on account of the heavy business, and death came suddenly while he was receiving a message from New York. Mr. Dennis was a man of high character and admired by all who knew him, and his sudden death is a shock to his many friends. Mr. Dennis was a thirty-three degree Mason, and the funeral services were attended by many Masons of prominence. The remains were buried at Morehead City, N. C.

Increasing the Membership of the T. M. B. A.

Dr. L. M. Rheem of Minneapolis, Minn., has taken active steps to increase the membership of the Telegraphers' Mutual Benefit Association in his section of the country and his plans for accomplishing this object are well worth careful consideration and adoption by others who have the welfare of the association at heart.

Dr. Rheem proposes to get the members in that agency together for consultation and then arrange to hold a few meetings at which as many eligibles from the telegraph and telephone companies as possible will be invited to attend. Appropriate addresses will be made, and enthusiasm and interest aroused. Dr. Rheem sees no reason why the membership cannot be increased from 1,000 to 2,000 during the next year if every one pulls a little.

It certainly is a unique idea and will no doubt be attended with successful results.

Every telegrapher should study the Lessons on Technical Telegraphy now running in TELEGRAPH AND TELEPHONE AGE. Subscription price, $2.00 per year.

A Joker in the Government Telegraph-Control Bill.

Congressman Carey of Milwaukee, Wis., who has distinguished himself in the government telegraph-ownership cause by introducing a bill in the House of Representatives at Washington, to accomplish the reality, has robbed the bill of some of its most interesting features by adding certain provisos. The measure stipulates that wages "shall not be increased more than 15 per cent over those paid the year preceding government acquisition."

Such a provision if carried out literally would prove to be a great hardship. It frequently happens in the course of telegraphic events that an operator is appointed to a superintendency, and if, in such a case, the salary is to be limited as Representative Carey provides in his bill, there will be a general strike against the acceptance of such promotions. Evidently the honorable gentleman never experienced such a sensation during his telegraphic career or he never would have placed such a stumbling block in the path of ambitious and worthy telegraphers who may enter the government service, if government control comes to pass.

The Reid Monument.

Following is a complete list of the representatives of the organizations named which are to meet as a committee of the whole to devise ways and means to raise funds for the purpose of erecting a suitable monument over the grave of the late James D. Reid in Mt. Hope Cemetery, Rochester, N. Y.:

The United States Military Telegraph Corps—David Homer Bates and Charles A. Tinker.

Postal Telegraph Club of Atlanta, Atlanta, Ga.—G. H. Usher and W. C. Daviet.

Serial Building Loan and Savings Institution, New York—James R. Beard and Edwin F. Howell.

New York Telegraphers' Aid Society—Thomas M. Brennan and Robt. J. Marrin.

Morse Club, New York—William J. Dealy and William Holmes.

Magnetic Club, New York—C. P. Bruch, A. B. Chandler and W. B. Dunn.

Association of Railway Telegraph Superintendents—L. B. Foley, F. G. Sherman and E. P. Griffith.

Old-Time Telegraphers and Historical Association—F. J. Scherrer and J. B. Taltavall.

A meeting of the committee will be held in February.

Dinner of Directors and Officers Serial Building Loan and Savings Institution.

The directors and officers of the Serial Building Loan and Savings Institution, New York, met at dinner at the Astor House, January 18, for the purpose of a general discussion of the affairs of the association. President A. G. Saylor being out of the city, vice-president James R. Beard presided.

Addresses were made by Messrs. C. P. Bruch, W. H. Baker, T. W. Carroll, E. M. Mulford, A. C. Terry, E. S. Butterfield and John A. Hill, on the subject of property valuations and the saving features of the association. All of the others present also made a few remarks. Mr. C. P. Bruch acted as toastmaster.

Several of those present pledged themselves to bring in at least fifty new members during the year, and as a result of this campaign over 100 new members have been added since January 1.

Those present were: Jas. R. Beard, Chas. P. Bruch, Thos. W. Carroll, E. M. Mulford, A. C. Terry, W. H. Baker, E. S. Butterfield, John A. Hill, T. M. Brennan, G. W. Blanchard, W. J. Quinn, E. E. Brannin, H. A. Konninger, C. A. Kilfoyle, E. F. Howell, T. E. Fleming, M. W. Rayens, M. J. O'Leary, J. T. Laidlaw, M. S. Cohen and W. B. Dunn.

Associated Press.

Mr. Charles Friedlander, traffic chief of the Associated Press at Chicago, Ill., was a recent New York visitor.

Mr. W. L. Waugh, dean of the press operators in this country, has returned to the New York Bureau after an absence of three months in recuperating his health. Mr. Waugh, who is one of the finest operators in the United States, has a new lease of life and is good for many more years of useful service to the Associated Press. He has been continuously employed in the news gathering service since 1878 and is one of the best known members of the newspaper staff in the country.

Trade Notes.

Bids Invited for Signal Corps Cable.—The Signal Corps of the United States Army is advertising for bids for thirty miles of single conductor cable intermediate, type 44. Bids will be received by Captain R. J. Burt, Signal Corps, U. S. A., until February 11.

Increase in Western Electric Company Sales Last Year.—The Western Electric Company's year, ended December, 1911, shows a total of $67,000,000 in goods billed out, or about 6% greater than the corresponding twelve months in 1910, and ranks as the second largest the company has experienced. Increased cost of labor and material, while the prices of manufactured articles have not advanced, have cut down the Western Electric's margins of profits in common with many industrials. The situation has been largely met by introducing operating economies and scientific management of manufacturing operations. At the close of the year there were about 24,000 persons on the pay-rolls.

Taxing Telegraph Lines in Nevada.—The Nevada state board of assessors has levied a rate of $40 a mile for each wire maintained by the Western Union and Postal Telegraph-Cable companies in Nevada.

Early Telegraph Days in Montana.

Recently a rancher in Montana received a cablegram from his partner in Australia the day before it was sent, this seeming paradox being due of course to the difference in time between the two points. This achievement led the Butte, Mont., *Inter Mountain* to compare the telegraph service of the present day to what it was in the early days of the West, when telegraphing was uncertain as regards the promptness of delivery at destination and operation. Several well-known old-time telegraphers are mentioned in the article, part of which we reproduce.

"After P. A. Largey and Count John A. Creighton built the first telegraph line into Montana in 1866 for the Western Union, it was not such a sure thing that a message filed today would reach its destination east of the Missouri river to-morrow, the next day, or later, although the company then charged $5 for a message of ten words. Telegraph line building was done and lines kept up under great difficulties during those early days.

"For instance, Levi S. Wild, the veteran manager of the Western Union at Butte, remembers when the buffalo covered the plains like leaves of grass, and in the Sun River valley, as the buffalo migrated south in the fall and north in the springtime, telegraph poles went down before them like reeds. There was no timber in the route of the buffalo migration, and the huge beasts welcomed the sight of the telegraph lines, for the poles offered an opportunity against which to rub their shaggy hides, and after the band of thousands had passed, the line had to be rebuilt.

"The telegraph company had other troubles of an unusual nature. There were snowstorms in Montana in the old days, storms and snowfalls of which the newcomers can have no idea. It was not uncommon to see a fall of snow, backed up by drifts, as high as the telegraph poles themselves. Linemen sent out to repair damages walked along on top of the snow, picked up the wires and had to stoop over to fasten them to their places at the top of the poles!

"The first telegraph line into Montana was built from Salt Lake to Virginia City, and followed the old stage route. The line was 470 miles long and touched at all the old stage stations of Ogden, Brigham City, Bear River, Malad, Ft. Hall, Old Eagle Rock, now Idaho Falls; Market Lake, Camas, Pleasant Valley in Montana, Ryan's station and other stopping places on the way to Virginia City.

"From Virginia City the line was extended to Helena in 1867, following along old Indian trails, down the Ruby valley to White Tail station, on to Boulder, over the divide, and down the Prickly Pear valley into Helena. Later the Government built a line from Helena to Ft. Shaw, Ft. Benton and to Ft. Ellis near Bozeman.

"The old overland line with its one wire was the only means of telegraph communication between Montana and the outside world until the completion of the Utah Northern Railway, now the Oregon Short Line, in 1878. Then the Western Union abandoned the old route and rebuilt its line along the railroad.

"The first manager at Virginia City, 1866, was Barney Hughes, and the following year Mr. Wild was sent there to assume charge. Mr. Wild made the trip from St. Joe, Mo., to Salt Lake on horseback, and he went on to San Francisco by stage and back again to Salt Lake, from which place he staged it to Virginia City.

"The great stretch of continent between the Atlantic and Pacific oceans, up to the completion of the Union Pacific in 1869, had only two telegraph wires as means of communication. The first line to San Francisco was completed in 1861. John A. Creighton of Omaha and the first Brigham Young of Salt Lake were partners in the construction of the line from Omaha to Salt Lake.

"In the half century since Mr. Wild first became a manager for the Western Union he has had experience that would fill a library. He fought his way through hostile Indians when he came West on horseback, and he rode for his life from a stampeding band of buffalo; he dug telegraph wires on top of high poles out of the snow, and was lost on plains and in forests, but he has an idea that the most strenuous time he ever had was a few years ago when, with the aid of one delivery clerk, he kept the Butte office of the Western Union going during the telegraphers' strike, receiving and sending from 350 to 500 messages a day."

The Telegraph Union Monument.—It was reported recently in the daily press that it was the intention to revise the decision of the international jury in accepting the design of Signor G. Romagnoli, of Bologna, Italy, for a monument to be erected at Berne, Switzerland, to commemorate the founding of the international telegraph union. We are informed officially by the director of the Bureau of the International Telegraph Union at Berne that the report is pure invention and that the jury which was unanimous sees no reason to change its decision.

The Johnson-Varley System of Tuned Telegraphy.—A demonstration was given in London recently by Messrs. Johnson and Varley of their tuned system of telegraphy, which they claim to be applicable to land wires, cables and wireless telegraphy. The tuning is acoustical, and is accomplished by the use of accurately constructed and standardized vibrating reeds, corresponding reeds being used in transmission and reception. Very great sharpness of tuning is attainable, as is instanced by the plans for a type-printing telegraph now under construction, in which the reeds controlling the forty-nine characters are all within the interval of one semitone. By the use of properly tuned relays, in conjunction with transmitters giving the corresponding notes, multiplex telegraphy is possible, and these may give in wireless telegraphy an additional safe-guard against interference and a means of increasing secrecy of communication.

Postal Company's New Type of Peg Switchboard.

BY JOHN F. SKIRROW, ASSOCIATE ELECTRICAL ENGINEER POSTAL TELEGRAPH-CABLE COMPANY, NEW YORK.

The Postal Telegraph-Cable Company's new type of peg switchboard for intermediate stations

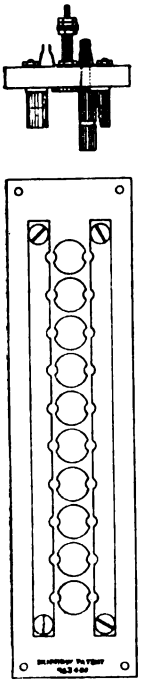

FIG. 1.—PEG SWITCHBOARD.

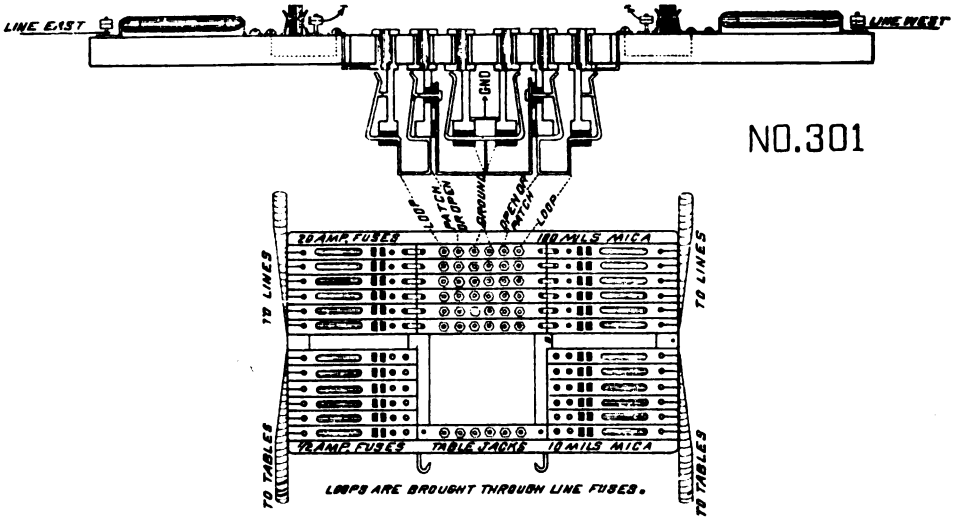
differs from those of other companies in mechanical construction but not in principle.

The Postal's intermediate peg switchboards are made up of slate units each holding two straps and ten rows of discs. (Fig. 1.) These units can be combined to make a board of any size which can be assembled locally and enlarged or decreased at will.

The pegs used are of standard telephone type instead of the taper pegs used in the regular type of peg switchboard. The holes are drilled clear through and contact springs are placed on the back of the discs and straps. The pegs are pushed through and engage with the springs insuring a good contact for either telegraph or telephone use.

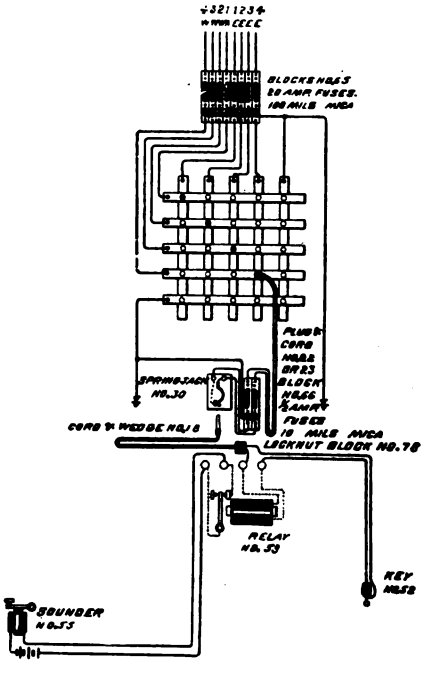
In addition to the peg switchboard described, the Postal Company uses a unit type intermediate board made up of porcelain blocks with "pin" or telephone-type jacks mounted in the blocks. Each of these blocks accommodates one wire in and out of the office. Two of the jacks are looping jacks, one to cut in east and the other to cut in west; two of the jacks are patching jacks east and west and the remaining two are grounding jacks east and west. Wires are grounded by inserting a telephone type plug in the grounding jacks, they are opened by inserting the same plug in the patching jacks, and they are patched with cords having a plug at each end, one plug being inserted in the patching jack of one wire and the other plug in the patching jack of the other wire. A double cord and plug connected to the instrument is used in the looping jack to cut the instrument in circuit. A knowledge of circuits is not necessary to operate this type of board. If the

Skirrow Patent 732012.



STANDARD SWITCHBOARD EQUIPMENT FOR OFFICES HAVING NOT OVER SIX LINES.

FIG. 2.—STANDARD SWITCHBOARD FOR SMALL OFFICES.



SWITCHBOARD EQUIPMENT WIRING OF CROSSBAR BOARDS

FIG. 3.—CROSS-BAR SWITCHBOARD.

plugs are inserted in the jacks as indicated in Fig. 2 the connections are made automatically. For convenience a diagram of the circuits through

Digitized by Google

the jacks is herewith shown. The circuits can be readily traced.

The Postal Company has a number of switchboards in service of a type known as the cross-bar. This board is made with a square wooden frame with vertical brass strips on the face of the frame and horizontal brass strips on the back of the frame. The distance between the front and the back strips is about two inches. The ends of incoming line wires are connected to the tops of the vertical strips on the face of the board. The ends of outgoing wires are connected to the horizontal strips on the back of the board. Holes are drilled in the front and back strips so that they come in line with each other wherever the strips cross each other. It will be seen that by inserting a peg through any holes at any cross-over, a front strip will be connected with a back strip, and an incoming wire thus connected with an outgoing wire. The connections can therefore be visibly traced with ease.

For connecting up instruments a double cord and peg is used, the upper half of the peg connecting with the front strip and the lower half of the peg connecting with the back strip, thus looping the instrument in between the front and back strips of the board. Fig. 3 shows the connections.

Policy of American Telephone and Telegraph Company with Reference to Independents.

Mr. Theo. N. Vail, president of the American Telephone and Telegraph Company, has issued a statement setting forth the policy of the company and its associated companies with respect to independent telephone companies.

The statement, which is dated January 5, reads as follows:

"In order that the American Telephone & Telegraph Company and its associated companies may follow the same policy with respect to maintaining toll connections with independent companies, it seems wise to state just what that policy is in this regard, and to advise the Associated Bell Companies and ask them to adopt the same for their guidance.

"FIRST. The Associated Bell Companies will extend toll line connections to any point or to any company where opposition exchanges do not exist, and where the result of such toll line connections would be a reasonable return upon the investment involved in the connection. The terms and conditions for transmitting or receiving toll or long-distance messages at such points shall be fair and equitable and as favorable as the terms and conditions extended to any other companies operating under similar conditions.

"SECOND. Should any Associated Bell Company acquire, by purchase or otherwise, any toll line which has connection with any independent exchange or toll line, all facilities enjoyed at the time of the acquisition by the independent exchanges or toll lines for sending or receiving messages shall be continued. When increased facilities shall be needed from time to time, such facilities shall be subject to future contracts which shall be made fair and equitable to both parties.

"THIRD. Should any Associated Bell Company acquire, by purchase or otherwise, any independent exchange property which has toll line connections, the Associated Bell Company will not cut off or disturb in any way such connections.

"FOURTH. It is to be understood that all existing connecting contracts or arrangements between independent companies, or between independent and Bell companies, shall continue without interruption should there be any change in the ownership, thus preserving the status of the situation.

"FIFTH. It is to be understood in all of the above cases that it is the wish and intention to preserve any facilities or connections which independent companies and their patrons may enjoy at the time the property of an independent company may be acquired, with such increase of the same facilities as may be necessary on account of future growth and extension of the business, but it is not the intention that by virtue of such acquisition, the range of facilities of any independent company or of the patrons of any independent company shall be increased.

"SIXTH. The Associated Bell Companies will not require connecting companies to use any special make of apparatus or equipment. The only requirement will be the use of such facilities and equipment as will give commercial service.

"SEVENTH. It is to be distinctly understood that this policy does not in any way contemplate physical connection between opposition exchanges, nor does it contemplate the interchange of messages between two or more exchanges located within the same town or community."

Telegraph Rates in Oklahoma Upheld.—The Oklahoma Supreme Court has set aside the telegraph rates for business within the State ordered by the Corporation Commission. This action was taken on the ground that the Commission's rates would not yield a fair return to the companies in Oklahoma. The court also modified the order by making it applicable to free deliveries within a radius of two miles of an office in incorporated cities only; also, as to the closing of offices in the State without the consent of the Commission, to an application to close on twenty days' notice.

Ferroconcrete Poles in New Zealand.—The Post and Telegraph Department of the New Zealand government is introducing telegraph poles and pillar letter boxes made of ferroconcrete. For ordinary straight lines the poles are six by eight inches at the base, six by six inches at the top and twenty-six feet long. Angle poles are eleven by eight inches at the base, eight by four inches at the top and 30 feet long, and are made hollow to reduce the weight.

Telephone Recording Tables in Philadelphia.

There has recently been placed in service in the Philadelphia Western Union office, says the *Journal of the Telegraph,* a telephone recording table to care for the large increase of telegrams received and delivered by telephone. During the short time that it has been in service the number of telegrams received by telephone has advanced 400 per cent. The use of the table has given the necessary accuracy and dispatch and assured the efficient handling of the telegrams.

The recording table consists of ten positions equipped with disappearing typewriter pedestal, pigeon holes for blank forms and a twenty trunk multiple, eight of which are at present in service.

TELEPHONE RECORDING TABLES AT PHILADELPHIA WESTERN UNION OFFICE.

The ultimate equipment is sixty trunks in which case the table would be increased to thirty positions, the design allowing for two trunk lines per position.

Each operator may take any call signalled by a white light. Busy trunks are shown by a green signal. There are two cord circuits at each position, one for answering and transmitting, and the second for reserve or for information purposes. Outgoing messages are delivered to the telegraph operator by means of a pneumatic tube and likewise the telegrams to be telephoned to the addressee are received through the tube.

It has been found that long-hand prepared forms, because of the necessary haste in writing them, are untidy and often nearly illegible, causing confusion and delay. Therefore the typewriter is used to record messages. In addition to the perfect legibility of its work, greater speed is thus obtained. An operator with only two weeks' experience on the typewriter has recorded ten messages, totaling 113 text words in an hour. The long-hand recorder has only been able to handle four messages or seventy-eight text words.

Transmitting Pictures by Telegraph. — *La Nature,* of Paris, describes a process of sending pictures over a telegraph line, using ordinary apparatus. The picture is divided into small squares and the quantity of light in each square is indicated by a number. These numbers are transmitted by wire and the corresponding parts assembled at the receiving station according to a definite plan.

An Operator in Love. — An ardent young Romeo in the West who, while not making love works as an operator, tried to compel the object of his affections to marry him by pointing a revolver at the girl. He was arrested and fined $100 for his display of affectionate zeal. Being an operator, however, he can pay the fine with ease.

CABLE ADDRESS: "Telegage," New York.
Telephone: 6657 Barclay

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

February 1, 1912.

Government Ownership of Telegraph Lines.

The recommendation of Postmaster-General Hitchcock that the government purchase and operate the existing telegraph lines has met with strong opposition from all quarters. There have been times in the past when the public mind would have accepted such a proposition more seriously, but, at the present, sentiment seems to be very strongly against it. Fully ninety percent of the newspapers who have thus far expressed an opinion on the subject are positively against the government ownership of the telegraphs.

Mr. Hitchcock endeavors to point out how the public will be benefited by government control of this important utility, but all of his arguments in favor of the proposition will not bear close analysis. For instance he says that lower rates will be possible because, among other things, there will be no taxes to pay, as private corporations are required to do, and the postoffices and telegraph offices can be consolidated, thus effecting a large saving in rent. What he says may be true from the government's standpoint, but what about the public—the party of the second part?

As far as taxation is concerned, it will simply shift the taxes from the private corporations to the public, should there be any deficiency, and there is every reason to believe that the government cannot operate the lines at a profit, notwithstanding the assertions to the contrary. England's experience with government controlled telegraphs may be taken as an example of what may be expected in this country if the government ever comes into possession of the lines.

Again, if the telegraphs are taken over the telephone systems must necessarily be included, because the telegraph and the telephone are so closely united that it would be extremely difficult to disjoint them and make two separate institutions of them.

Reverting to the question of taxation an interesting fact should be kept in mind in connection with this proposition. A very small percentage of the people use the telegraph, and it is proposed to tax all the people for the benefit of the few who use it. Will the American people agree to such a proposition? The government telegraph department would soon become a huge machine, burdened with charges of all sorts, and these burdens would of course have to be borne by the people.

The proposition to close independent telegraph offices and combine the service with the post-office would certainly not meet with public favor. The private companies establish branch offices for public convenience, but the government would close many of these, and the public would be required to travel longer distances to reach a telegraph office, or telephone instead. But could they telephone their messages if the government did not own the telephone too?

Under government ownership invention would stagnate. Uncle Sam never buys an invention. He simply appropriates what he needs, and the inventor has no redress.

The question of damages for errors in messages is also a very important one to consider. What redress would a person have in such cases if the government operated the telegraph?

These and many other questions of a practical character come to mind in considering Mr. Hitchcock's scheme, which may be all right in theory, but in practice it is extremely questionable whether it would prove to be such a boon as its projectors think it would be. It is highly interesting and significant that the public has expressed so positively what it thinks of the matter, and, although the good sense of the people may be relied upon in the last analysis, it will be necessary for their champions to be wide awake and on the defensive at all times.

The United States and the Radio-Telegraph Treaty.

Although the United States Government took an active part in the treaty of the International Radio-telegraph Conference held at Berlin in 1906, it has not as yet confirmed the treaty. As the conference to be held at London on June 4 is a plenary one, the United States will not be invited to send representatives unless the Berlin treaty should be confirmed previous to that date.

The situation at this time is as follows: The international wireless-telegraph business of the world is conducted under a treaty signed at Berlin on November 3, 1906. As the United States up to this time has not given its adherence to the convention, ships flying the American flag find themselves without standing in international wireless telegraphy, as none of the contracting countries is compelled to receive a telegram from the ship of a non-contracting country, and any

Digitized by Google

coastal station in a foreign country may refuse transmission of a message to a station on shipboard subject to a non-contracting country.

A dispatch from Washington states that on January 18 the wireless treaty was referred back to the Senate Committee on Foreign Relations for renewed recommendation. The treaty was favorably reported to the Sixtieth Congress, but the session adjourned without action upon it. In view of the London conference an endeavor is to be made to secure the adherence of the United States to the treaty before that time.

The Genesis of Public Service Commissions.

Many of the States now maintain public service commissions whose duties are to watch public service corporations and see that they maintain reasonable rates and commit no illegal act. Such corporations include railroad telegraph, telephone and other companies.

Public service may be conducted by the government or by private individuals, but there is a great difference in the powers of the two classes. The government has no one to get after it with a sharp stick while the private corporation is being continually watched. Almost every business man has ground for complaint against the Post Office department for instance, for the loss of letters, etc., but that service being under the protection of the government generally escapes public censure. The aggrieved individual must submit to such inconveniences and losses with equanimity for the public good. Public service corporations are at the mercy of the government. It fixes rates and prescribes rules with little regard to financial consequences, and the result is a general disturbance and uneasiness in business affairs.

Public service legislation originated in trivial complaints, which, when ventilated through the press, became exaggerated beyond all proportions. Many fictitious crimes were laid at the doors of public service companies, the people got excited and the legislatures were compelled to take cognizance of the cause of all the trouble. We do not mean by this that we believe that private individuals or corporations are, like some kings, incapable of committing a wrong. It is right that they should keep within reasonable bounds in dealing with the public, but they also have rights which should be respected.

It is noteworthy that the investigations of the public service commissions have, as a rule, failed to find any abuse of power on the part of electrical companies. The commissions have learned that railroad, telegraph and telephone companies are efficiently managed and that their charges for the service rendered are on the whole, reasonable.

Public clamor results in much mischief, and it is extremely unfortunate that selfish interests should promote and maintain such unreasonable action. Yet these things are always with us and vested interests are compelled to do the best they can under the circumstances.

While of course it is inadvisable to attempt to undo what has been done there is an evident reaction in public sentiment and a tendency to deal less harshly with public service companies. After sober, second thought, public opinion, so-called, is beginning to recognize the principle of fair play. Misunderstanding is the cause of most all individual and corporate troubles, and if each of the parties at issue would only endeavor to view the matter in dispute from the standpoint of the other, they would arrive at a rational understanding of the situation and settle their difficulties without resorting to oppression or warfare.

Is Telegraphy an Art or a Science?

A correspondent asks if we are correct in referring to telegraphy as an art and not a science.

The only way we can pass upon the question is to refer to the standard definitions of these two words. The Century dictionary defines science as "knowledge gained by systematic observation, experiment and reasoning; knowledge co-ordinated, arranged and systematized."

Art is defined as "the employment of given means to effect a purpose; an especial facility in performing an operation, intellectual or physical, acquired by experience or study."

"The object of science is knowledge; the objects of art are works."

These definitions are taken directly from the dictionary and are not tainted in the least degree by personal belief or opinion; they are what all men accept as standard. It requires little consideration of the matter to understand that our use of the word "Art" is correct.

One can practice an art but cannot practice a science.

Canadian Pacific Promotions.

In looking over the list of promotions in the telegraph service of the Canadian Pacific Railway Company one is impressed with the fact that reward for merit and fidelity seems to be the predominating feature. When a vacancy or other change occurs, the great wheel moves forward one cog, the resulting vacant position being filled from the lower ranks, those in front being advanced correspondingly.

It must be a feeling of great satisfaction to the members of the telegraph staff of this company to know that faithful and intelligent service will bring its reward. Every official position, from the highest down, is filled by a former telegrapher, and it is safe to say that each occupant holds his position because he is entitled to it by reason of fidelity to duty and loyalty to the company. So great and important a corporation as is the Canadian Pacific Railway Company must have the very best of material in every department for its successful operation.

Operators in Demand for Navy.—There is an urgent demand for enlisted men in the United States Navy who are telegraphers, wireless operators particularly.

Course of Instruction in the Elements of Technical Telegraphy—VIII.

(*Copyrighted.*)

(Continued from page 48, January 16.)

[We began in our issue for October 16 the publication of a course of instruction in technical telegraphy. The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and is divided into chapters, following one another in logical order.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases, and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.]

Electricity.

POTENTIAL, CURRENT, RESISTANCE.

The peculiar charm of a trout stream lies in the delightful variety of water scenes it affords to the angler. Here we have the noisy, rushing rapid with its foam-streaked pool below, there the quiet run with stones and tailing eddies, yonder the placid still-water marking the level meadowland.

The current strength, or the rate of flow of the water, depends in each case upon the height through which the water falls in a given distance, and with a uniform channel it is only necessary to establish a certain difference in level to produce a current of any required strength.

Similarly a current of electricity will flow with almost imperceptible strength, or with the rush and power of Niagara, if the required difference in electrical level, or potential, be provided, but it must be understood that the current thus obtained is not a material current like the stream, for it possesses neither weight nor extension. It is not matter, but simply a condition of matter, and the statement that electricity is flowing through a wire is only another way of expressing the fact that the wire and the space surrounding it are in different conditions than usual, and that they possess unusual properties. The action of electricity, however, is quite similar in many respects to the flow of liquids, and the study of electric currents is much simplified by the analogy.

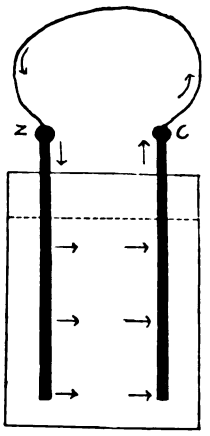
The zero, or normal water level, is taken as that of the surface of the sea. The zero of electrical potential is the earth itself, an electrical level or potential higher than zero being called positive, and a potential below zero, or lower than the earth, negative. The direction of current flow is, like the stream, always from the higher to the lower level or potential.

A difference of potential may be obtained by placing two dissimilar metals such as copper and zinc in contact. Place the tip of the tongue between a silver quarter and a copper cent, allowing the coins to remain in contact, and the peculiar taste experienced will denote the presence of an electric current resulting from the difference of potential developed by the dissimilar metals.

The same results will follow if the plates are slightly separated from each other and placed in a vessel containing acidulated water, leaving a small portion of one end of each plate exposed. A vessel containing two dissimilar metals immersed in this manner is termed a voltaic cell, and the metals are called the voltaic elements. The liquid is called the electrolyte.

There is now a difference of potential between the exposed ends of the plates, the copper exhibiting a positive potential, or a pressure higher than that of the earth, and the zinc a negative potential. Connect the two exposed ends with a wire and the potential inequality will tend to equalize, or come to the same level, and in doing so will produce a momentary current. This equalization of potential will be instantaneous, and unless a further difference of potential can be obtained, the current will cease after a momentary flow. But the effect of this momentary current passing through the cell is to cause certain chemical changes, which, in turn, cause a new difference of potential, resulting in another momentary flow of current; and since these actions follow each other with inconceivable rapidity, the result is a practically continuous current.

The exposed copper and zinc are, as before stated, positive and negative respectively, and consequently the electrodes or poles—the metallic



FLOW OF CURRENT WITHIN AND OUTSIDE OF A CELL OF BATTERY.

terminals of the plates to which the wire leading to the next cell or apparatus is connected—are of similar polarity, but with the submerged ends the opposite conditions exist, namely, a negative charge on the copper and a positive charge on the zinc. The current, therefore, will flow from the exposed end of the copper, or positive pole, through the connecting wire to the zinc, or negative pole, and from the submerged end of the zinc through the electrolyte to the submerged end of the copper.

Digitized by Google

The current is maintained by the chemical action which takes place between the zinc and the electrolyte. The copper serves mainly as a means of connecting the external circuit to the electrolyte, the other end of the circuit being connected to the zinc.

(*To be continued.*)

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. There is a general demand for knowledge on the quadruplex, duplex, etc., and to aid in the acquirement of such knowledge we are extending our help to students by asking questions on these subjects in each issue of our journal, so that they may be encouraged in their studies by answering them. We use as our textbook Maver and Davis' "The Quadruplex," and students should have a copy of this book at hand in order to be able to give the answers. The questions are progressive and a careful reading of the book on the points under inquiry unfolds the answers. This method of acquiring technical knowledge is a fascinating one.]

WHEATSTONE SYSTEM (*Continued*).

How are the two levers of the transmitter kept in an upright position?

Do the two levers move the same distance to the right?

What is the function of the clockwork in the transmitter box?

How is the upward motion of the levers regulated?

How is the disc D divided and connected with the circuit?

What is the purpose of the metal pins on the disc?

How does the disc change the line polarity from positive to negative and from negative to positive?

What is the purpose of the star-wheel in the transmitter?

How is movement imparted to the star-wheel?

What is the marking current?

How many impulses are sent to line in forming a dot?

How many times do the levers move per minute in transmitting at a speed of 250 words per minute.

Where is the polarized relay located in the receiving apparatus?

How is the paper roller operated?

What is the function of the governor on the receiving instrument?

When there is no current to line what position does the polarized-relay armature assume?

What action takes place when a positive or spacing current is connected to line?

What action takes place when a positive or marking current is sent to line?

How is the armature of the polarized relay adjusted?

ANSWERS TO QUESTIONS.

[In this department questions on matters of a practical character, and of general interest, will be answered. Questions intended for this department must be signed by the writer's full name—not for publication, but for identity. No attention will be paid to anonymous communications.]

(85) Q. You occasionally print references to the relief fund of the New York Telegrapher's Aid Society. I would like to know how this fund is created and administered, if you will kindly explain. I. W. L.

A. In a large city like New York there are always some members of the telegraph fraternity who, for one reason or another, cannot be admitted to membership in this society. In times of sickness these persons are cared for and in the event of death proper burial is provided. The relief fund bears such expenses. It is maintained entirely by voluntary contributions and its financial operations are kept separate from those of the aid society. Each year the society gives an entertainment and ball for the benefit of the relief fund.

(86) Q. How are wireless signals sent from station A to station B, and from station C to station D without interfering with one another? A. C. L.

A. This is accomplished by what is called "tuning," or varying the frequency of the transmitter. If the B station is tuned to respond to signals of a definite frequency sent from A, and D to respond to signals of another frequency from C, there will be no interference. The transatlantic system of the Marconi Company is worked duplex in this way, and it is furthermore practicable to send two messages from A to B at the same time.

Electrical Instruments and Testing.

Every one connected with the telegraph and telephone service should know how to test lines and also be familiar with the instruments used in such work. It does not require much study to learn the mechanical operations of this important branch of the service, but of course a knowledge of electrical and mechanical principles involved in the design and construction of the instruments, and of the principles involved in measurements is the source of deep and never-ending pleasure to the ambitious student.

An excellent book on this subject, intended for the practical man, is "Electrical Instruments and Testing," by Norman H. Schneider, with new chapters on testing wires and cables and locating faults, written by Jesse Hargrave, division superintendent of the Postal Telegraph-Cable Company, Atlanta, Ga.

The price of this book is $1.00 and copies can be had of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York. Any other book on telegraph, telephone or general electrical subjects can be obtained at the same place.

Fifty Years Ago.

BY WALTER P. PHILLIPS.

In my recent article in the *New York Times.* which TELEGRAPH AND TELEPHONE AGE did me the honor to reproduce in its issue of December 16, I refrained from going into many particulars as to individuals, thinking I might take up some of these later. Among the many interesting men employed by the American Telegraph Company, first at No. 21 Wall Street, New York, and later at No. 145 Broadway, was Nelson D. Pratt now a wire merchant in Chicago. I first met him in Providence fifty years ago, the eleventh of last May. The wire with which he was associated in those days was not an inspiring affair and did not have anything like the possibilities in it for the youthful Pratt possessed by the wire proposition in which he has been interested for many years past. It ran from New York to Fall River via most of the towns along the New York and New Haven Railroad in both New York and Connecticut and it was very liberally represented in the state of Rhode Island by River Point, Providence, Warren and Bristol. When he was unable to get circuit on this leaky old wire which was designated as No. 5 he would go over to another one on which the printing system was used and make himself useful there. Number 5 was a difficult circuit at best, and was rendered more so by William P. Potter, manager of the office at Fall River. He had ideas on the subject of right of way and he had the courage of his convictions and was willing to fight circuit the year around rather than let anybody in on the wire as long as Fall River had even one message to go.

Providence had formerly been on another wire which went to New York via New London and New Haven, and its interpolation on No. 5 was not relished by Mr. Potter. He claimed that Providence should not be there at all but superintendent Wood did not share that view so the "little giant," as he was sometimes called, was often thwarted in his intention to run the whole show. He was such an insistent circuit-struggler that it is related of him that getting into trouble with some small office whose manager had rigged up a circuit into which the pendulum of a clock was connected, he fought all night. The philosophically minded manager had simply gone home and left the clock in circuit. When he came to the office the next morning the first thing he did was to cut out the clock, and this was what greeted him: "Another time when you want to fight circuit with me you had better not try it, but close up shop; go home and get some sleep. No one can beat me out at this game. "PFR."

After the absorption of the American Telegraph Company by the Western Union in 1866, an order was issued instructing all operators to adopt a signature, or sign letter, and to send it over the line at the end of each message. This rule has since been changed as we all know, and the signature is sent now at the beginning of messages. Almost every one signed a single letter but the very first day the new rule was in effect Mr. Potter appeared on the scene with a three-lettered signature—P for Potter and FR for Fall River. He desired everybody to know that he was no ordinary potter but William P. Potter of Fall River. So the signature went forth and became famous. It was known all over the country.

Various imitators of Mr. Potter's somewhat mincing but quite fast and pretty sending rose up, among them Preston J. Hurlburt of Providence. His imitations were the best, but all of us were more or less versed in the art. Hurlburt had all of Potter's ways down fine and no one could detect him in the act of committing these forgeries in the second degree. There were many turnpike wires in New England which had been bought up by the Western Union and one of Mr. Potter's little side line enterprises was the keeping of a horse and wagon which he farmed out to the Western Union as needed for the use of the linemen sent out for trouble on defective circuits. At about the time Mr. Potter went to his luncheon one was liable to hear Fall River calling New Bedford at a great rate and presently Benoni Paine the manager would respond. He and Potter had been messengers together in Providence many years before and were great chums. Hurlburt would say; "When my man gets there, put my horse in the stable give him six quarts of oats, and don't take his harness off. PFR."

These fictitious commands, having the very air of authority that were imparted to them when they were really given by Mr. Potter, led to many misunderstandings between him and his friend Paine, but they were none the less heartily enjoyed by the precious scamps who did the telegraphing in Providence during and after the civil war, and those stationed along the line who were familiar with the eccentricities of "three lettered jack," as he was sometimes called. As No. 5 became more and more congested, in later years, Fall River was permitted to come in on the through wire between New York and Newport and when the regular operator at Fall River went to luncheon PFR took the wire and as long as he was permitted to send he was on safe ground, being a tuneful sender who separated the spaced letters in a particularly intelligent way and who got over the ground at a lively pace.

For years PFR regarded himself as the best and fastest sender in New England and he only yielded the palm, at last, when Burns and Kettles made some time records that left him in the shade. But when it came to receiving he developed an obvious weakness. His handwriting was small and graceful but not adapted to being put on paper at more than fifteen or eighteen words per minute. He was constantly in hot water with everybody who sent even two-thirds as fast as he did, and his general complaint was that the sender "stuck," a phrase that was also woven into the telegraphic parlance of the time together with the

Digitized by Google

six quarts of oats that went with the horse whose harness was to be kept on.

Probably a more contentious little man over the wire never existed, but *in propria persona* he was a dear good fellow. He used to visit Providence, quite frequently, and on one occasion he said to me in strict confidence, "Walter, I think I can send a little faster than any man can receive." A few years later, on August 7, 1864, I was in Taunton, over Sunday, and PFR called up and said there had been a great Union victory. The *Fall River News* which was publishing a morning edition, temporarily, had columns of the story, but there was no way to get Fall River or Boston or Providence papers to Taunton, on Sunday, in those days. So PFR said he would send the news if it were desired, and Charles Crandall, the manager of the office, replied very promptly that he wanted the best synopsis of it that could be sent in a couple of hours, and Mr. Potter got started about half past nine o'clock.

For some time previously Farragut had been adding fresh lustre to his fame by his operations around Mobile and on the Friday preceding the Sabbath day on which PFR was to distinguish himself in such a striking manner, Farragut's fleet, reinforced by four monitors, had made a savage attack on Fort Morgan in Mobile Bay. The Admiral lashed his fourteen wooden ships together in pairs, and at six o'clock in the morning the long line steamed into Mobile.

"As they drifted on their path
There was silence deep as death;
And the boldest held his breath
For a time."

The above is from Campbell's Battle of the Baltic, but it applies with equal force to Admiral Farragut's start through the narrow passage of Fort Morgan. The monitors steamed ahead, cautiously, and the other ships, slowing down, dropped back from the rest of the squadron. The strong current carried them across the channel and the long line of ships curled itself up directly under a raking fire from Fort Morgan. No one held his breath after that and the fight was on in earnest.

The smoke from the guns was so great that the Admiral climbed into the shrouds of his flagship, the "Hartford," to get a better view of the struggle, and as he went higher and higher, his position seemed so perilous that a man was sent up to fasten him in his place. Fort Gaines was taken, but the expected capture of Fort Morgan was deferred for nearly three weeks when it yielded to a bombardment. The port of Mobile was henceforth closed to Confederate commerce, though the city, itself, did not capitulate until the the following April. News had been arriving in driblets for several days, but it was not until the night of Saturday, August 6, the day after Farragut, when warned of the presence of torpedoes in the channel, had signalled the reply, "Damn the torpedoes!" that with the probable assistance of a smuggled copy of the *Mobile Register* and such data as he could secure from other sources, the Associated Press correspondent, with Farragut, got his graphic story on the wires. It was very interesting and gave the Sunday papers an August sensation that was thrilling in the extreme, notwithstanding the terribly hot weather that prevailed from Mobile Bay to the New England coast.

The Associated Press writer confidently predicted the fall of Mobile, within a few days, but we had to wait seven or eight months for his prediction to come true. The chances are that he drew on his imagination quite liberally for southern newspapers, even if he had been well supplied with them, did not afford great opportunities for the judicious use of the scissors. They were always reticent when the battle was going against the South. The occasions when the southern press were well supplied with news, foreign and domestic, was whenever somebody got a copy of the *New York Herald* through the lines and delivered it into the hands of Frank West, the representative of the Associated Press at Richmond. His son was once an employe of mine, in Washington, and he was well supplied with stories his father used to tell about news gathering, on the Confederate side, in war times, and the extravagance with which the southern papers ordered the news and the reckless prices they were willing to pay for it. "Send everything the *Herald* has and will ship money at once," was the conventional formula, according to the younger West. "Why, sir, at the end of the war," he would conclude, "my father had more Confederate money than any man in the South. Yes, sir, and he would have had ten times as much, if he hadn't refused to pay the freight charges on most of it."

Mr. Crandall, who was a magnificent receiver, invited me, in very seductive tones, to sit in while he went for a flour barrel that he intended to have used for some one to stand on and read the despatches to a multitude that he knew, from previous experience, would quickly gather when the report began to spread that vital war news was to be received. As he was the manager of the office and I the guest of one of his operators, whose experience had not been sufficient to enable him to take press reports, I could scarcely decline, and before I knew it, PFR was piling the stuff into me at a gait that must have pleased him exceedingly, although it did not quite agree with me. The day was suffocating and I was done up in my full individual allotment of the cuffs and collars, white vests and spats, that go with youths of eighteen. I was not happy and the excitable Potter increased his steam capacity like a locomotive, when he was fairly under way. He had got a break out of Crandall in 1857 and had been laying for him ever since, hoping to score another one against him, and this was his golden opportunity. He knew nothing about the change in operators, and he was in his element, for he had two or three hours of sending to do and was in no danger of having to receive anything. The only man, singular as it may seem, whom Crandall could find to mount the flour barrel and read the despatches, was himself, and the bravery of the boy who stood on the burning deck of his father's flag-

Digitized by Google

ship at The Battle of the Nile in obedience to the French admiral's command, yielded no more gracefully to the voice of parental authority than Crandall acquiesced in the expressed wishes of his auditors as they cried, now and again, "Give us some of that stuff over again, Charlie," or "Go on, old man and read us a lot more," etc.

As I emerged from the sweat box in which I had been imprisoned for more than two hours, which had seemed like a hundred and two, the church services were ending, and people were pouring into the streets from many directions While they had been at worship the reports of the stirring events in far away Alabama which had been taking place during several preceding days, had been drifting over from Fall River, on the wings of the morning, and Crandall, as he saw me approaching with the final pages of copy in my hand, striking a Roman senator attitude, on the head of a flour barrel, was a cheering sight to see, under the circumstances, with his constantly increasing congregation listening to his news with all the ears they possessed.

Charles was something of a wag. In replying to a question which PFR asked me, quite early in the proceedings, I made some unconscious revelation of myself, and after that he let out his last link. But it was all in vain for I was just as stubborn as he was and would not have broken him for worlds. He was very gracious when he finished the 5,000 or more words he had sent me, and observed: "I take back what I said to you once, in Providence. Let me revise it and put it this way: I believe you can receive faster than any man can send." He little knew what was in store for me when the new crop of senders should come to the front. He did not see his finish, then, but he was convinced when he heard Kettles send that he had never been in it, from first to last, and that he was a back number, with all which that eloquent phrase implies.

In 1862 Pratt went to New York and his presence in the principal office of the American Telegraph Company was marked by his selection as one of those chosen to receive President Lincoln's message to Congress in 1863. There were eight of these men and the message was divided into eight parts so exactly alike, in size, that all of the Washington senders finished at the same moment. The whole document was handled in fifty-two minutes, and before the last of it had been delivered to the newspapers, boys were on the street crying their "extras," and shouting that their papers contained the President's message. Of course only the first part of the message was given, but to have any of it in print before the work of telegraphing it from Washington was finished was regarded, fifty years ago, as a feat of surpassing magnitude. Presidential messages are supposed to be presented to Congress as soon after the members meet at noon, as is consistent with the making of the daily prayer by the chaplain, and the reading of the journal, but, on this occasion, although eight of the best operators in the world were in readiness to do their part, the message was not ready for transmission, until 2 p.m., and no pains was spared to keep them at their desks until the message was disposed of.

Not only "men must work and women must weep," as we are assured by Canon Kingsley, but telegraph men must eat. Knowing this the managers of that day provided the waiting octette with an acceptable supply of food which did not come from Delmonico's by any means, although Lorenzo Delmonico, "the original Jacobs," had his restaurants in the neighborhood and a particularly fine one in Beaver Street, where I remember going, as a boy, to view the marble pillars which had been excavated at Pompeii and brought to New York at great expense. I had read Bulwer's "Last Days," and anything that had come from the scene of his wonderful story had more attractions for me than all the tempting viands that his talented chefs could produce and all the famous wines contained in the cobwebbed bottles or the dust laden flagons and fiascos hidden away in Delmonico's well stored cellars.

Mr. Pratt, much to the regret of all his friends, left the telegraph business in the summer of 1864, but as long as he remained he was a vital part of the operating force at No. 145 Broadway as he had been at No. 21 Wall Street where the general telegraph office had been located up to the early part of the year 1861. Among other interesting despatches that passed through his hands in 1863-4, was one from an agonized father in Maine, who wired to Senator Fessenden asking him to see President Lincoln and intercede for a delay in the execution of his son, for sleeping on post, which was appointed for the next morning at six o'clock. The father asked that action might be deferred until he could reach Washington.

The files of the War Department are filled with the notes, letters and telegrams from Mr. Lincoln to military officials ordering stays in cases such as the one in which Senator Fessenden's correspondent was interested. Burnside might lose the day at Fredericksburg, McClellan win at Antietam, Greeley cry aloud for the emancipation of the slaves before Lincoln was ready to break their shackles, Grant might capture Vicksburg, or anything else that was vital might happen, this great man, his eyes ever roaming from point to point, and his mind as active, ingenious and commanding as that of Caesar or Napoleon, always found time to extend a succoring hand, or speak a kindly word and to do all that it was within human power to do for the unfortunate soldier, however humble he might be. In that respect he rose superior to every great commander in the world's history and revealed a love for his fellow man that the horrors of war and the demands upon his time and attention could not change excepting to strengthen it.

About the time referred to the records show the appended despatches and quite likely one of these was written in response to the pleading message

Digitized by Google

that passed through Mr. Pratt's hands en route from a heartsore parent in Maine to the man who represented his state, in the Senate, with such great distinction from 1854 until his death in 1869:

Washington, D. C., Dec. 3, 1863.

Major General Meade:

Please suspend sentence in the case of William A. Gammon, Seventh Maine and send record to me.

A. Lincoln.

Washington, D. C., Dec. 14, 1863.

Please suspend execution in the case of William Gibson, Fourth Maine, until further notice and send record.

A. Lincoln.

January 28, 1864.

To the Commanding Officer,
At Fort Preble,
Portland, Maine.

Suspend the execution of the death sentence of Charles Caple, set for tomorrow, until further orders and forward record for examination.

A. Lincoln.

Telephone Pioneers of America.

F. H. BETHELL.

Mr. Frank H. Bethell, vice-president of the New York Telephone Company, who, as announced in our issue for January 16, was elected president of the Bell Telephone Company of

FRANK H. BETHELL (1890).

Pennsylvania, The Delaware & Atlantic Telegraph & Telephone Company, The Diamond State Telephone Company, The Chesapeake & Potomac Telephone Company and The Central District & Printing Telegraph Company, assumes these important positions well equipped with experience and natural ability.

Mr. Bethell entered the telephone service in November, 1890, as a messenger for the New York & New Jersey Telephone Company at Newark, N. J., and in the following January was appointed to a position in the auditor's office of the Metropolitan Telephone & Telegraph Company in New York. In July, 1901, he became contract agent of the New York Telephone Company and in 1904 he was appointed general manager of The Chesapeake & Potomac Telephone Company with headquaters at Washington, D. C, Mr. Bethell's duties were further increased in 1906 when he went to Philadelphia as vice-president of The Bell Telephone Company of Pennsylvania and associated companies. In February, 1908, he became president of the Maryland Telephone Company, which previous to that date had operated as a competing company in the state of Maryland, and in 1910, he was elected vice-president of The Central District & Printing Telegraph Company. Mr. Bethell is now president of all of these companies as noted, with headquarters in New York, and under his direction they will get the benefit of a ripe experience and sound judgment.

It is not often that so many honors are bestowed upon so young a man, but Mr. Bethell has proved his ability and the telephone company has not been slow in recognizing his worth and using it. He is well versed in the science of organization and is very popular.

Mr. Bethell is vice-president of the Telephone Pioneers of America and takes an active interest in its affairs, as he does in all things he undertakes.

Decision in Regard to Telegraph-Telephone Office at Watervliet, N. Y.

An interesting decision has been rendered by the Public Service Commission, second district, New York, with reference to telegraph facilities in the city of Watervliet, N. Y.

The Western Union Telegraph Company closed its office in that city and arranged to handle its business through a telephone station. A complaint was made to the Commission, requesting that a city office with a telegraph operator be maintained.

The Commission in dismissing the complaint states that free delivery of telephones has been extended over the entire city limits of Watervliet; that a telephone office will be maintained in charge of an agent of the Western Union Telegraph Company, and that telegraph messages will be transmitted by telephone to Troy, in a closed booth to preserve secrecy. It is also provided that the Western Union Company shall display a sign on the outside of the building showing that it maintains an office at that point.

Mr. L. Derrick, of Philadelphia, Pa., in renewing his subscription for another year, writes: "This is one way I have of remembering myself at Christmas and to my mind the one best gift."

Telephone Train Dispatching in 1911.

Almost every issue of TELEGRAPH AND TELEPHONE AGE during 1911 recorded the introduction or extension of telephone train dispatching on one or more roads, and the ordinary plain system of telegraphy seems to be going out of fashion. Dispatching of trains by telephone has proved to be so reliable and efficient that there can be no reasonable doubt that all the railroads in the United States will finally be equipped with a system of this character.

Compared with the telegraph method the consensus of opinion among railway telegraph superintendents is that the telephone system is far superior and effects gains in many ways, particularly in time, which is one of the most important factors in railway operation.

With a view to ascertaining what has been done along these lines we invited all the railway telegraph superintendents in the country to state what progress they had made in the past year and what plans were laid down for extensions, etc., during the new year. Following are some of the replies:

Mr. Charles Selden, general inspector of transportation and superintendent of telegraph, Baltimore & Ohio Railroad, Baltimore, Md.: "During the year 1911 we have strung a telephone train dispatching circuit and in addition a telephone message circuit, covering 512 road-miles, and the equipment is just being installed for operation. We have had in service for almost a year a train dispatching circuit on one division, and the results were so satisfactory that it has been decided to add to this service every month during 1912. It is the intention and expectation that by the end of 1912 the entire Baltimore & Ohio Southwestern Grand Division, 980 road-miles, will have been provided with a telephone train dispatching circuit and a telephone message circuit in addition, and the probability is that within the year 1912 all of the single track portions of the Baltimore & Ohio system will be so arranged."

Mr. S. A. D. Forristall, superintendent of telegraph of the Boston & Maine Railroad, Boston, Mass.: "The Boston & Maine Railroad did not extend its telephone dispatching system during 1911. We have three circuits at present and they are giving satisfaction in every particular. We expect, during the coming year, to install two or three more circuits."

Mr. W. F. Williams, superintendent of telegraph Seaboard Air Line, Portsmouth, Va.: "The Seaboard Air Line Railway, with a mileage of 3,100, has 1,100 miles of train dispatching by telephone, and we will very likely complete the whole in the course of time, but at this writing I have no authority for future extensions. We have found the telephone to be a great saver in train time, and I am now preparing some figures showing a comparison in this respect."

Mr. L. B. Foley, superintendent of telegraph Delaware, Lackawanna & Western Railroad Company, New York: "The Delaware, Lackawanna & Western Railroad Company is entirely equipped with selective telephone dispatchers' circuits and the telegraph is no longer used for dispatching purposes. We also have three telephone message circuits on which messages are handled by telephone instead of the Morse. We have three hundred selectors in use and fifty-two telephone booths at freight sidings, where train men can communicate with the dispatchers and obtain information or orders. We have ten dispatching circuits with a mileage of 1,001 miles. Our entire dispatching system, being operated by telephone, we contemplate, during the year 1912, installing additional telephone message circuits and several hundred miles of railroad commercial telephone circuits."

Mr. E. C. Keenan, superintendent of telegraph, New York Central Lines, Cleveland, Ohio: "On the Lake Shore & Michigan Southern, Lake Erie & Western and Toledo & Ohio Central systems, we practically completed last year the construction and installation of telephone train dispatching circuits and equipment on all divisions, having covered all of the main lines. The construction of new telephone circuits gave us added Morse facilities, which have been utilized for through service, so that the telegraph and telephone circuits now provided and arranged for give adequate facilities for satisfactorily handling the railroad business."

Mr. J. F. Caskey, superintendent of telegraph, Lehigh Valley Railroad Company, South Bethlehem, Pa.: "Two telephone train dispatching circuits, were installed and put in operation on the entire Wyoming division, 260 miles of single and double track, making 520 wire miles. A yard dispatching circuit covering the New York division, between Jersey City and Newark, distance sixteen miles or thirty-two wire miles was installed and put into service. A train-dispatching circuit covering the entire Pottsville branch, forty miles or eighty wire miles, were installed and put into service, the line being attached to the Lehigh division dispatching circuit. To accomplish this forty miles of pole line were rebuilt, the old line being unreliable. Three hundred and fifty Western Electric portable telephones and line poles were installed on cabooses and baggage cars, covering the entire portion of the road now equipped with train dispatching circuits, which includes the territory between Jersey City, N. J., and Sayre, Pa., a distance of 270 miles. These telephones are found very effective during derailments, delays, etc., saving the time of train crews. Rail gangs, bridge and section forces, have also been supplied with this apparatus which enables them to work their men on closer time by being thoroughly informed as to the progress of trains over the section of road on which they are engaged. We a about completing the rebuilding of 125 miles of pole line between Burdett and Depew, N. Y., erecting forty twenty-five-foot poles per mile, aiming for a low line to prevent trouble during storms and to

Digitized by Google

enable the train crews to reach the telephone lines without difficulty when necessary to use the portable telephones and line poles. We have in course of erection two train dispatching circuits to cover the entire Buffalo division, 352 miles. These lines will be ready for service some time during the coming spring. When these lines are erected we will install on all cabooses and baggage cars, between Sayre, Pa., and Buffalo, N. Y., 140 portable telephones and line poles, so that each train running over the road will be able to reach the dispatcher without delay. During the coming summer we expect to erect a train dispatching circuit on the Elmira and Cortland branch, between Elmira and Camden, a distance of 140 miles—280 wire miles."

Mr. J. B. Murphy, superintendent of telegraph, Southern Railway Company in Mississippi, Jackson, Tenn.: "We did not improve our telegraph facilities any during the past year. There is some talk of a telephone circuit during the present year, but realization is doubtful."

Mr. G. O. Perkins, superintendent of telegraph, Chicago Great Western Railroad Company, Chicago, Ill.: "During 1911 the Chicago Great Western Railroad inaugurated on its eastern division two telephone dispatching circuits and two telephone message circuits each equipped with thirty-five selectors and from forty to sixty telephones. The dispatchers' circuits are simplexed and a through telegraph circuit worked over them. A grounded phantom telephone circuit is also worked over the wires of the two dispatcher's circuits giving a through telephone circuit and a through telegraph circuit and two local dispatching circuits on one pair of wires between Chicago and Oelwein. The grounded phantom was designed by Mr. W. L. Cook of the United States Electric Company. On the western division telegraphones have been installed at all important stations and are carried on all freight and all passenger trains. On the northern division telegraphones have been installed at all important stations. On the southern division a telegraphone circuit was established between Oelwein, Iowa, and Des Moines, Iowa, a distance of 132 miles on a No. 8 iron wire on a heavy lead, most of the wires of which are quadruplexed, and where the inductive disturbances were so great that telegraphone communication had been considered impracticable even for short distances. This circuit is equipped with special instruments designed by Mr. H. O. Rugh of the Sandwich Electric Company. I regard the new devices by Messrs. Cook and Rugh as very important advances in the art of communication."

Mr. George Boyce, superintendent telegraph and signals, Chicago, St. Paul, Minneapolis and Omaha Railway Company, St. Paul, Minn.: "We have no telephone train dispatching circuits as yet."

Mr. W. S. Melton, superintendent of telegraph, Queen and Crescent Route, Danville, Ky.: "The Cincinnati, New Orleans & Texas Pacific Railway built two parallel telephone circuits between Danville, Ky., and Oakdale, Tenn., during 1911, one of which is a dispatcher's circuit and the other a message circuit. From an efficiency standpoint these circuits have exceeded the expectations of the transportation officials."

Mr. B. F. Frobes, superintendent of telegraph, Oregon Short Line Railroad Company, Salt Lake City, Utah: "We have made no progress in telephone installation during the year 1911 on our line. The only installation we have is a short one between Salt Lake and Ogden, which is badly affected by induction from power transmission lines and we have not been doing very well on account of this. The leakage from these power lines seems to interfere with the satisfactory working of selectors of any make."

Mr. W. J. Camp, assistant manager, Canadian Pacific Railway Company's Telegraph, Montreal, Que.: "During the year 1911 the Canadian Pacific Railway Company's telegraph department added to its equipment nearly 5,000 miles of copper wire and 1,500 miles of iron wire for telegraph service, 1,750 miles of telephone dispatching circuits, 100 miles of other telephone circuits and about 400 miles of pole line, with two or more wires over new branches. It has also installed a storage battery plant at Moose Jaw, Sask., and a dynamo plant at Saskatoon, Sask., besides increasing the dynamo equipment at Ottawa and Fort William. The erection of a 16-story office building in Toronto has also been commenced. About 1,200 miles of old line have been rebuilt besides general repairs over other lines. During the whole season there have been between 600 and 700 men employed in extra gangs doing this work."

Mr. J. J. Ross, superintendent of telegraph, Michigan Central Railroad Company, Detroit, Mich.: "Very little was done in the year 1911 in the way of extensions or improvements in the telegraph or telephone. The present mileage is divided into nine dispatching circuits all of which are giving excellent satisfaction, and we expect to add at least four more dispatching circuits this year. It is hoped that we will also be able to put up a few message circuits."

C. J. Steinel, superintendent of telegraph, San Pedro, Los Angeles & Salt Lake Railroad Company, Los Angeles, Cal.: "During the year 1911 we were engaged in rehabilitating our lines through a part of southern Nevada where, in former years, we had suffered greatly from washouts. The new line has been placed in solid rock and high up out of reach of anything less than a general deluge. This work entailed an enormous expense so there was little opportunity to devote to the development of modern systems of telephony for train dispatching, or for experiments of an innovating character."

Every one connected with the telegraph and telephone services should read Telegraph and Telephone Age.

Digitized by Google

Mr. E. P. Griffith, superintendent of telegraph, Erie Railroad Company, Jersey City, N. J.: "There have been no additions made on the Erie Railroad since the time covered by the report in your issue of June 16, 1911, but several additional circuits are under consideration."

H. D. Teed, superintendent of telegraph, St. Louis & San Francisco Railroad Company, Springfield, Mo.: "It is very probable that this company will extend its telephone dispatching and accompanying message circuit approximately three hundred track miles during the coming year, in order to relieve a congested territory."

(To be continued.)

Government Ownership of Telegraph Lines.

Announcement was made from Washington on January 14 that Postmaster-General Hitchcock would submit to Congress a plan for acquiring the telegraph lines by the government to be operated as part of the postal service. This, it appears, was done without first submitting the matter to the Cabinet, and a statement has been issued from the White House to the effect that as the report containing the recommendation has not yet been submitted to the President, it has not been considered by him or by the Cabinet with a view to presenting it to Congress as an Administration measure.

Mr. Hitchcock stated that he had made a thorough study of the subject and was convinced that if his recommendation were adopted it would result in important economies and very materially lower telegraph rates that now are exacted. "In approximately fifty countries of the world," he said, "notably in Great Britain, France, Germany, Austria, Italy, Spain, Russia, and Japan—government-controlled telegraphs now are in successful and profitable operation. In many of the countries they are operated in connection with the postal service. These telegraphs serve an aggregate population of 950,000,000, and in every instance they have been found to be of immense practical benefit to the people, in both promptitude and cost of the service.

"In this country Post Offices are maintained in numerous places not reached by the telegraph systems, and the proposed consolidation, therefore, would afford a favorable opportunity for the wide extension of telegraphic facilities. In many small towns where the telegraph companies have offices the telegraph and mail business could be handled readily by the same employes. It is evident that the separate maintenance of the two services under present conditions results in a needless expense.

"The first telegraph in the United States was operated from 1844 to 1847 by the government, under authority from Congress, and from many viewpoints it is desirable that government control should be resumed.

"My own view," Mr. Hitchcock continues, "is that every reason for the transmission of mail under government control can be urged with equal force for the transmission of communications by telegraph. Because of the more extensive organization maintained by the Postal service and the freedom from taxation and other charges to which private corporations are subject, the government undoubtedly could afford greater facilities at lower rates than are afforded by companies now conducting the telegraph business. Next to the introduction of a general parcel-post, for which there is a strong popular demand, the establishment of a government telegraph system offers, in my judgment, the best opportunity for the profitable extension of the nation's postal service."

It is not Mr. Hitchcock's purpose to recommend the acquisition of telephone lines, except possibly in instances where they are operated as telegraph lines and are an integral part of definite telegraph systems.

The latest census figures available indicate that about 100,000 persons are connected with the telegraph companies of the United States. The appraised value of the systems proposed to be acquired would be purely conjectural, but it is said it would approximate $250,000,000.

Mr. Theo. N. Vail, president of the Western Union Telegraph Company, in commenting on Mr. Hitchcock's proposition said he did not think the government would do such a thing. "The expense the British government has been under," he said, "in maintaining the telegraph lines, should indicate that public ownership is not very promising and I should not think our government would find very much to enthuse over if Congress will read the last report on the cost over on that side of the ocean. The last annual report of the Western Union Telegraph Company refers to the situation in England where the general revenue pays just about one-half the cost of conducting the telegraph lines. In other words the expense of handling every message exceeds the amount received about 50 per cent."

Mr. Clarence H. Mackay, president of the Postal Telegraph-Cable Company, New York, stated that government control of the telegraph would be unprofitable.

"The step would lead to taking over the telephone lines also," Mr. Mackay said. "The British government found this to be so, and on January 1 it took over the telephone lines in England at an enormous expense.

"The telegraph and telephone lines in this country are worth two billion dollars to three billion dollars. This would include the independent telephone companies having some 450,000 stockholders.

"I venture to say that they would be operated by the government at a great annual loss, just as in Great Britain, where the losses on the telegraph alone up to date are figured at $175,000,000. Moreover, the government would then be employing hundreds of thousands of clerks, telephone girls telegraph operators, managers, etc. It would be a colossal political machine."

Mr. E. J. Nally, vice-president and general manager of the Postal Telegraph-Cable Company, New York, gave it as his opinion that "the country is not quite prepared for such a step. If the government is to take over our public utilities shouldn't the big-

Digitized by Google

ger things be taken first? Surely the railroads are bigger than the telegraph."

All of the New York daily newspapers, with one exception, and the papers throughout the country, editorially express themselves against government ownership of the telegraphs.

Representative Carey, of Wisconsin, (an old-time telegrapher,) on January 19 introduced a bill in the House providing for government ownership of telegraph lines. The bill recites that the telegraph systems be placed under the supervision of the Post Office Department in charge of a Commissioner of Telegraphs, to be appointed in the same manner as assistant postmasters general. It also provides that the Inter-State Commerce Commission appraise at their bona fide market value all the telegraph properties engaged in Inter-State commerce, the attorney-general then to begin condemnation proceedings against the companies. The measure stipulates that wages should not be increased more than 15 per cent. over those paid the year preceding government acquisition, and bars any immediate decrease of telegraph tolls.

Many telegraphers favor government ownership of telegraph lines, believing that they will receive higher pay, shorter hours of labor, an annual vacation and pension on retirement from active service.

W. J. Camp, Assistant Manager of Telegraphs, Canadian Pacific Railway Company.

Mr. William J. Camp recently appointed assistant manager of telegraphs of the Canadian Pacific Railway Company with headquarters at Montreal, has reached this high position through merit and unflinching fidelity to his trust. He is a Canadian by birth and experience and is a leader in his line of activity.

Mr. Camp was born at Oakville, Ontario, April 22, 1855. At the age of sixteen he was obliged to leave school permanently, and for the following three years engaged in different kinds of employment including bookkeeping and various duties in a saw mill and in the freight office of the Grand Trunk Railway at Prescott, Ont. Here he learned telegraphy and entered the service of the Dominion Telegraph Company as operator in that place in September, 1874, and then took up the study of wire testing and switching. In the following spring he moved to Montreal and became chief bookkeeper in the office of the Grand Trunk and in the summer of 1876 became manager of the Watertown, N. Y., office, but left the service toward the end of the year and was temporarily employed at various points on the New York Central Railway, Troy & Boston Railway, Atlantic & Pacific Telegraph Company and the Western Union Telegraph Company at Albany, N. Y. He left the latter company to re-enter the service of the Dominion Telegraph Company at Montreal in the summer of 1877, becoming night chief. In January, 1878, he became train dispatcher on a line which is now a portion of the Canadian Pacific Railway. When this road was seized by the government he returned to the position as night chief in the Dominion Telegraph Company's office being later advanced to the position of assistant day chief. On the consolidation of the Dominion and Montreal Telegraph companies in 1881 under the name of the Great North Western Telegraph Company, he was made local electrician at Montreal and filled this position until July, 1883. He then became operator for the Canadian Pacific Railway at Hochelaga and in September, 1884, he received the appointment of superintendent of the Holmes Electric Burglar Company at Montreal. He held this position until April, 1886, when he re-entered the service of the Canadian Pacific Railway as chief electrician over the whole system for the telegraph department which had recently been

W. J. CAMP,
Assistant Manager of Telegraph, Canadian Pacific Railway, Montreal, Can.

formed. In December, 1899, he succeeded Mr. James Kent as superintendent of the Eastern Division which then covered the territory between Port Arthur, Ont., and Louisburg, Cape Breton. In November, 1903, he was appointed electrical engineer for the whole system, which position he held until his promotion on January 1 this year to be assistant manager of telegraphs.

The keynote of Mr. Camp's success has always been "attention to business" and it may be said of him that he considered himself always on duty. He has the happy faculty of making business a pleasure. He is an active and popular member of the Association of Railway Telegraph Superintendents and was its president during the year 1908-09.

Mr. W. I. Sweet, assistant chief of Division of Telegraphs and Telephones, Public Service Commission, Second District, New York, says in reference to renewal of subscription to TELEGRAPH AND TELEPHONE AGE: "Our office would be at a serious loss without this magazine on our files."

Digitized by Google

Telephone Companies in New York State.

The annual report of the Public Service Commission, second district, New York, for 1911, says with reference to telephone companies: The jurisdiction of the Commission was extended in September, 1910, to telegraph and telephone corporations, and the work of supervision of these corporations is now fully organized. As a result of inspection by Commission employes, a vast number of defects in operating efficiency and methods, as well as of the equipment, lines and apparatus, has been found in telephone plants. During the year, 424 central offices serving 372,860 sub-stations have been inspected.

Attention is called to the exemption of telephone companies having property of less than $10,000 in value which do not come within the jurisdiction of the Commission. The Commission has no power to make an examination of the property of a company which claims to be without its jurisdiction, and it is possible for companies to organize with less than $10,000 of stock and obtain a foothold in communities without any regulation or supervision whatever by the Commission, and thereby defeat the real purpose of telephone regulation.

Further attention is called to the fact that under the law as it stands the stock of one telephone corporation can be purchased by another without application to or authorization by the Commission, or local plants can be transferred in the same manner. Companies in most cases can be consolidated or merged in precisely the same manner as before telephone companies were placed under the jurisdiction of the Commission.

Attention is also called to the tendency to consolidation among telephone companies of importance. The Legislature is asked to note that if any evil is in this policy, measures to correct the same should be taken.

Gold & Stock Life Insurance Association Annual Meeting.

The thirty-fourth annual meeting of the Gold & Stock Life Insurance Association was held in New York, January 15. Mr. G. W. E. Atkins, president, in his report said that in reviewing the work of the association each year one is impressed by the immense amount of good that has been accomplished in the distribution of the benefits accruing from the privileges of membership in it, and with the lesson that has been taught, and which will continue to manifest itself through the beneficent influences of fraternal co-operation. He said that $149,300 has been distributed to the association's beneficiaries to date.

In closing he referred to his having been president of the association for ten years, and expressed regret that he had for some time been prevented by other duties from doing more than a small part of the work of the association, but that in the future while he could always be called upon, he hoped that he would not be expected to do more than a member's share. He appealed to the members to continue their good work in the direction of increasing the resources and enlarging the scope and benefits of the association.

Mr. Lewis Dresdner, treasurer, in his report showed $10,325 paid to beneficiaries during the past year. Balance in the treasury, $17,217.34.

Mr. Atkins' desire being well known that the first vice-president should now be advanced to the presidency, several of the members present spoke in the warmest terms of appreciation of the work that Mr. Atkins has done during the past ten years, and in due course, suitable resolutions were passed, expressive of such appreciation.

The following officers were then elected: Gardner Irving, president; Charles Shirley, vice-president; William J. Dealy, secretary; Lewis Dresdner, treasurer; Herbert Smith, Thomas A. McCammon, Michael Breslin, Albert J. Driver, Herbert M. Heffner, executive committee; Michael J. O'Leary, Frederick J. Nurnberg, James A. Sweeney, auditing committee.

Association of Broker Telegraphers.—The Association of Broker Telegraphers of New York is doing good work in a quiet way for Wall Street bankers and brokers. Whenever a vacancy occurs in the ranks of the broker-telegraphers the brokerage firm concerned looks to the association to recommend a competent man to fill the position, and the results of this policy are uniformly satisfactory to both parties. The association has on its list the pick of the profession and its work in behalf of the brokers has gained for it a high standing among this class of employers. Mr. C. L. Hall is the secretary of the association, Mr. T. L. Mahan, chairman, and J. B. McKeever, treasurer. It was recently stated in one of the New York newspapers that the members of this association were in favor of government ownership of the telegraph lines, but this report, Mr. Mahan states, is not true. A large majority of them are in favor of private ownership and this, he says, is true of the brokers themselves, reports to the contrary notwithstanding.

Wants Branch Office Every Five Blocks.—An alderman in one of the cities recently proposed a resolution asking for a better telegraph service. When asked as to what he considered a better telegraph service he said he thought that the telegraph company should be compelled to open a branch office every five blocks so that any one wishing to send a telegram would not have far to walk. This gentleman evidently has not the slightest idea how few people in the residential section of a city ever have occasion to send a telegram, although they use the telephone almost every hour in the day.

Telegraph in Uruguay.—The Uruguayan government has authorized an expenditure of nearly $400,000 in improving the state telegraph lines.

The Railroad.

Mr. G. A. Cellar, superintendent of telegraph, Pennsylvania Lines West of Pittsburg, Pittsburg, Pa., was a New York visitor, January 19.

Mr. L. S. Wells, superintendent of telegraph of the Long Island Railroad Company, New York, is absent on a few weeks' vacation on account of ill health.

Dr. B. D. Caldwell, vice-president of the Delaware, Lackawanna & Western Railroad, has resigned the position to accept the presidency of the Wells Fargo Express Company with headquarters in New York. Mr. Caldwell is well known in telegraph and railroad circles and is an executive of great ability.

Mr. G. H. Corse, Jr., has been appointed general passenger agent of the San Francisco Overland Route, with headquarters at Yokohama, Japan, the Oriental Agency of the Chicago, Milwaukee & St. Paul Railway at Shanghai, China, having been abolished. Mr. Corse's territory covers eastern Siberia, China, Japan, Philippine Islands and India. He is a well-known member of the telegraph profession and was a recent visitor in New York.

Meeting of New York Central Telegraph Superintendents.—The regular quarterly meeting of the superintendents of telegraph of the New York Central Lines, was held at the Grand Central station, New York, on January 18, and matters pertaining to the general service were discussed. The superintendents present were: A. B. Taylor, superintendent of telegraph, New York Central & Hudson River Railroad, New York; W. W. Ryder, general superintendent New York Central Lines, Chicago; E. C. Keenan, superintendent of telegraph, Lake Shore & Michigan Southern Railway, Lake Erie & Western Railroad and Toledo & Ohio Central Railway, Cleveland, Ohio; L. A. Lee, superintendent of telegraph, Pittsburg & Lake Erie Railroad, Pittsburg, Pa.; and J. J. Ross, superintendent of telegraph, Michigan Central Railway, Detroit, Mich.

W. M. Godsoe, Superintendent Atlantic Division, Canadian Pacific Railway Company's Telegraph, St. John, N. B.

Mr. Walter M. Godsoe, recently appointed superintendent of the Atlantic Division of the Canadian Pacific Railway Company's telegraph, with headquarters at St. John, N. B., was born in St. John, January 2, 1876, and has always resided in his native country. He entered the telegraph service at Dorchester, N. B., September 11, 1890, as agent, afterwards occuping the position of operator at St. John, N. B. In 1896 he went to Halifax, N. S., as night chief, later becoming chief operator, and in 1902 local manager of the office, which latter position he occupied at the time of his recent appointment to a superintendency.

Mr. Godsoe is a man of wide experience and assumes his new position well qualified to meet the duties of the office.

Canadian Pacific Telegraph Appointments.

The Canadian Pacific Railway Company may be likened to a school or a family. The higher officials have reached their present positions of trust through the lower grades, and it is the policy of the company in every branch of its service, including the telegraph, to recognize merit and reward faithful service.

In the January 16 issue we published a list of some of the more important promotions in that company's telegraph service on January 1. In addition to these we have since received a list of other promotions as follows:

F. E. Camp, inspector at Revelstoke, B. C., has been transferred to Nelson, B. C.; Geo. Wady, general foreman, has been appointed inspector at Revel-

W. M. GODSOE.
Superintendent Canadian Pacific Railway Company's Telegraph, St. John, N. B.

stoke, B. C.; D. L. Howard, chief operator at Calgary, Alb., to be inspector at Cranbrook, B. C.; J. J. Schetgen, manager Calgary, to be inspector at Medicine Hat, Alb.; S. M. Thurston, circuit manager at Moosejaw to be inspector at Regina, Sask; W. Rutherford, manager Winnipeg, Man., to be inspector at Souris, Man.; W. J. Van Every, operators, to be night chief, assistant night chief and assistant traffic chief, respectively, at Toronto, Ont.

The Late E. N. Dennis.

The announcement of the death at Richmond, Va., on January 15, of Edward N. Dennis caused regret throughout wide telegraphic circles, and to his personal friends was the source of sincere sorrow. To know him was to admire a man of sterling qualities and to love him for his genial, gentle nature. Few men have been marked by greater individuality, and, while he was sociable and charitable in disposition, he was quick to discern the genuine and the worthy, and had but little in common with pretentious mediocrity. He was a gentleman of pure mind, methodical habits, dignified bearing, yet withal one having a keen sense of humor; was approachable and cordial in manner, intelligent and dignified in conversation, and universally respected.

Mr. Dennis was born fifty-five years ago in Morehead City, N. C., of sturdy Scotch-Irish parentage. He early developed into a superior operator, and during the early seventies worked in Richmond, Va., Houston, Tex., Washington, D. C., and New York. In 1879 he returned to Richmond, and for many years copied the night Associated Press report, his presence on the wire being known only by his response to the office call and his "sign." About fifteen years ago he became night wire chief and shortly afterwards was created night chief operator, which position he held at the time of his death. He declined other positions, and his relations with the operating department continued unbroken for more than thirty years. He usually worked three or four hours daily at the key, and it was while thus engaged that the vital spark suddenly left him and his hands fell lifeless to his side. He was lifted by tender hands and borne to the rear of the operating room while a physician was summoned. Death, however, had been instantaneous. His remains were turned over to the Masonic order, of which he was a thirty-third degree member. A weird but impressive midnight service was held in his honor by members of the Scottish Rite, after which his remains were forwarded to Morehead City, to be buried alongside those of his father. They were accompanied by delegations from his Masonic lodge and the Western Union office, Messrs. Veale, Murphy and White representing the company.

Mr. Dennis was the last of a long line, his mother having only recently died at the advanced age of ninety years. He had accumulated considerable property, and it was doubtless his intention to spend his last days in comfortable retirement, but that time never came, and he laid down his life in harness faithful to duty even to the supreme moment.

An Operator Who Turned Reporter.

Mr. I. A. Davis, an operator who had been doing relief work at Charleston, S. C., during the two weeks prior to the disastrous hurricane which swept the South Atlantic coast last August, says the *Associated Press Service Bulletin*, deserves great credit for his good judgment and voluntary zeal in his efforts to get news of conditions in Charleston to the outside world.

Mr. Davis had finished his work for the Associated Press and was preparing to leave the city when the storm came. Early Monday afternoon, August 28, he was in the Western Union office talking with the operators when he heard the chief operator giving instructions concerning a proposed trip to Summerville, a small village twenty-two miles out from the city, on the Southern Railway, where it was hoped communication could be established with one of the nearby cities. He obtained permission to go along and exacted a promise of the use of a wire if the Western Union was successful in restoring the wires to working order.

With this feature of his trip settled, Mr. Davis's next thought was what he would do with the wire if he got it. He puzzled his brain until the party boarded the train for Summerville, then he quickly decided to write a story *en route* and have it ready for transmission the moment he got the wire. He is a rapid writer, and by the time his destination had been reached, he had put together a story of about a thousand words.

It did not take the Western Union long to find a good wire, which they turned over to Mr. Davis, and within a short time he had climbed a pole and sent out a comprehensive description of the chaotic conditions in Charleston.

After he finished sending his story, he proceeded to outdo himself by copying with a pencil the report being sent on the regular Associated Press circuit. How difficult a feat this is, but few people outside of the telegraph field realize.

In appreciation of Davis' splendid work, he was substantially rewarded and assigned to a regular position in the Atlanta office.

Mr. W. S. Barker, district plant superintendent, Western Union Telegraph Company, Boston, Mass., in renewing his subscription, writes: "You say that you have renewed my subscription and you ask if your action meets with my approval. I consider the editorial page alone worth the subscription price; therefore, I approve of your action and enclose my check covering said approval."

THE MOST SUCCESSFUL ELEMENTARY WORK.

A B C OF ELECTRICITY

By WM. H. MEADOWCROFT

One volume, 12mo. cloth, 50 cents. Fully Illustrated.

This excellent primary book has taken the first place in elementary scientific works. It has received the endorsement of Thos. A. Edison. It is for every person desiring a knowledge of electricity, and is written in simple style, so that a child can understand the work. It is what its title implies, the first flight of steps in electricity.

Meeting of Western Union Chapter, Telephone and Telegraph Society of New England.

Mr. A. G. Saylor, general superintendent, Eastern Division, Western Union Telegraph Company, New York, delivered an interesting address at a meeting in Boston on January 25 of the Western Union Chapter of the Telephone and Telegraph Society of New England. He was in a happy, reminiscent mood, and his remarks were interspersed with a number of humorous stories in connection with the service and occasion.

The early struggles of Professor Morse and his close personal friend and partner, Mr. Alfred Vail, during the period between 1835 and 1837, in inventing the telegraph, was referred to as well as the first successful experimental trial over a short circuit, which was established in the building occupied by the Vail Iron Works, Morristown, N. J., on January 6, 1838. Mention was made of the fact that Mr. Alfred Vail was undoubtedly the first person to read the Morse characters by sound.

A brief review was given of the early struggles of Prof. Morse and Mr. Vail to induce private capital to become interested in the development of the telegraph, to the end that its practicability and commercial value could be demonstrated, and how, finally, an appeal was made to Congress for an appropriation of $30,000 for the purpose of constructing a main line wire, with the result, after many months of pleading, the House of Representatives finally passed the appropriation bill on February 23, 1843, only to learn that then but small hope existed for favorable consideration by the Senate.

Without discouragement, the efforts to secure the appropriation were renewed, both Prof. Morse and Mr. Vail having unbounded faith in their enterprise, and a short time after the date mentioned, Prof. Morse, while seated at breakfast, was congratulated by Miss Annie G. Ellsworth, daughter of the Commissioner of Patents, who said: "Prof Morse, the Senate last night voted you $30,000." The value of this great invention to the civilized world, and the impetus given in the development of the nations was brought out.

Reference was made to the farewell dinner given to Prof. Morse in New York, June 11, 1871, a short time before his death, and the message of greeting and thanks to the telegraph fraternity throughout the world, which on this occasion was transmitted by Miss Sadie E. Cornwall, the signature being sent by Professor Morse, from an instrument specially provided and connecting with the telegraph circuits throughout the continent, the message reading as follows: "Greeting and thanks to the telegraph fraternity throughout the world. Glory to God in the Highest. On earth peace. Good will to men.

"S. F. B. Morse."

Referring to his connection with the telegraph, Mr. Saylor said that he entered the service in 1871 at Ingersoll, Ontario, and recalled that at this time Prof. Alexander Graham Bell was working upon his invention of the telephone at Brantford, Ont., a few miles distant from Ingersoll. At a later period, Mr. Saylor stated, while an operator with the Western Union at Portland, Me., he had an opportunity, in 1876, to become one of the pioneers of the telephone, but missed the opportunity for the reason that in being tendered the first position given for the purpose of establishing an exchange, or what was then termed securing a few subscribers, part of the salary was to be paid in telephone stock, which to a young man at that period had but little attraction.

However, he partially excused his failure to appreciate the opportunity which was lost by relating the story told by Prof. Bell at the meeting of the Pioneers of the Telephone held at Boston last November, Prof. Bell stating that the practical working of the invention was exhibited at the Centennial Exposition in Philadelphia, in 1876, but the success of the exhibit had to depend upon his assistant, Prof. Bell having a more important engagement with a student body at Boston; and how the assistant finally succeeded in making the apparatus work, the evening before the Commissioners of Award examined the invention, and as a result the success of the telephone was heralded throughout the world.

Mr. Saylor repeated the story, which is told of Mr. Chauncey M. Depew, who, it is stated, in 1877 declined to take over a half interest in the Bell patents for the sum of $25,000 or $30,000, after conferring with the then president of the Western Union Telegraph Company, Mr. William Orton; all of which tended to show what heroic struggles were necessary to develop both the telegraph and telephone in the early periods, when their value was but little known and not generally recognized.

Reference was made to Mr. Theo. N. Vail's experience and knowledge of the telegraph from its early period to the present time and his great experience, grasp and conception of the telephone service. Mr. Saylor brought out the fact that Mr. Vail was the only logical mind to direct those great enterprises and bring about a construction epoch in the interests of better service to the public and an improvement in the conditions of the personnel of the telegraph forces.

The commercial features of the Western Union Telegraph Company were not referred to, and in a brief, statistical way it was shown that the telegraph, segregated as it was, from a close affiliation with the telephone was, with the great development of the telephone, becoming more and more a partial and incomplete service, and not a complete, prompt and satisfactory service to the general public. This was due, he said, to the wonderful progress and usefulness of the telephone, and to the commercial and social development of the country, and it was Mr. Vail who recognized the great possibilities of a universal telephone-telegraph service—one complementary to the other, one an auxiliary to the other, each working within its own field, but both interchangeably and each completing promptly the service performed only by the other—to the end that the telegraph company may more satisfactorily serve the public as a public service corporation. This, Mr. Saylor stated, was his personal view of the situation, and, so far as the Eastern Division

Digitized by Google

was concerned, he could do but little to carry to a successful conclusion the great constructive work now undertaken by President Vail and his able executives. At the same time, however, he was proud of the Eastern Division organization, considering the opportunities heretofore afforded those engaged in the telegraph business during his forty-one years' experience, and he was satisfied that the division is working as one unit with a great spirit of co-operation, and, with this condition existing, he had no concern as to the results.

Mr. Saylor referred to the resolution passed by the Board of Directors in March, 1910, and to the confidence and interest which has been taken in the personnel of the forces of the company as expressed in the resolution, and was glad to say that the employes of the division had both confidence and faith in the management, and looked with much satisfaction upon the great work which is being undertaken.

Feeling reference was made to the faithfulness and spirit of fraternal kinship existing among the older members of the craft, and an expression of thanks was given the society for their invitation to him to be present, as such occasions gave him an opportunity to meet many old friends among the New England people—within the telegraph and telephone service.

Death of Henry L. Storke.

Henry L. Storke, aged 69 years, a well-known telephone pioneer, died in New York on January 27. In 1879 Mr. Storke became assistant general manager of the Western Union's telephone lines. The next year he helped in the organization of the first telephone company operating in Chili and Peru, and later organized the Central New York Telephone Company at Utica, the Telephone Company of Missouri, and the National Telephone Exchange Association. He was postmaster at Auburn, N. Y., for five years. He retired from the telephone business in 1902.

Transfer of the English Telephone Service to the Postoffice.

At midnight on December 31, 1911, the British government took formal possession of the 600,000 telephones owned by the National Telephones Company and thereby assumed actual operation and control of all public telephones in the United Kingdom, and the 18,000 employes of the National Telephone Company. The employes will now be protected by civil service against the loss of positions and enjoy the rights of post-office department employes to pensions, sick benefits and annual vacations. The government now has an absolute monopoly of all public means of communication by mail, telephone and telegraph.

The government, which has had a commission of experts studying the telephone service of other countries, especially in the United States, promises to introduce many new improvements and give better service at a lower cost. Already telephones are being installed in private houses in London, giving subscribers the benefit of a single party wire for $25 a year. Subscribers at this rate are entitled to call any other subscriber in an area embracing a population of over 7,000,000. No ceremonies marked the transfer.

The price which the government will pay for the old company's property is not yet determined. It is being fixed by a commission which is taking an inventory and will base a decision on the actual value of the property.

Establishing a New Office in Quick Time.—Some rapid construction work was done by the Western Union Telegraph Company when its office in the Equitable building at 120 Broadway, New York, was destroyed by the fire of January 9. By 11 o'clock the same morning the commercial department had secured quarters for a new office in the Trinity Building, 111 Broadway, and before 4 p. m. the plant department had supplied the necessary fixtures to fit up the office, connected up the wires, erected signs, etc., and the traffic department had sufficient force ready to take hold as soon as the equipment was ready. By 8 o'clock the next morning the American District Telegraph call circuits were all in operation. The three functional departments worked together harmoniously in this emergency and business was resumed in the new quarters with slight interruption.

New York Telephone Society.—At the meeting of the New York Telephone Society on January 24 Mr. H. G. Kerr, division commercial manager, Westchester district, New York, made an address on the subject of handling telegrams by telephone. Fourteen telephone operators are now employed in taking telegrams by telephone at 195 Broadway, whereas six months ago only three operators were employed. Mr. R. S. Scarburgh, special agent, New York, described the commercial end of the telephone service. Mr. Scarburgh presided.

Telegraph Managers Subpoenaed.—The managers of telegraph offices in over a dozen different cities have been subpoenaed to appear before the Federal grand jury at Indianapolis, Ind., to testify in the investigation of the dynamite conspiracy which, it is said, was directed by telegraph by J. J. McNamara, who is now serving sentence for complicity in the *Los Angeles Times* dynamite explosion.

Nebraska Telephone Injunction Dismissed.—The Nebraska supreme court has dismissed the injunction suit brought by that State to prevent the American Telephone & Telegraph Company from purchasing the independent telephone exchanges at Plattsmouth, Nebraska City and Papilion, Neb.

Fire Alarms by Telephone.—The cities of Ann Arbor and Ypsilanti, Mich., use the regular telephone exchange in sending alarms of fire, and it is stated the method works successfully.

Cash Registers in Telegraph Offices.

In a recent issue we referred to the introduction of cash registers in New Zealand telegraph offices. Further information regarding the use of these machines will be of general interest in telegraph circles.

The cash register constructed for the New Zealand telegraph department automatically tabulates all classes of telegrams and shows at any minute the total of each kind of message, as it contains a number of sets of adding wheels, showing the total amount as well as the total number each of prepaid, urgent, ordinary, collect, and press messages. In addition, it prints on the message which the sender hands over the counter the kind of telegram, the date, the number, the office of origin, and amount of cash paid. The amount is also shown to the sender of the message on wheels, which come up each time and are visible to the clerk as well as to the sender of the message. No message will be accepted by the operator and sent without having the amount printed thereon showing that it has been put through the register. A detailed record of this information is printed on a strip of paper which is, when in use, concealed under lock, just the same as all totals.

The wheels can all be set to zero, or only certain totals set back, allowing others to accumulate the amount for an indefinite period. The machine also has inside a secret total where all amounts which are recorded are accumulated. This can be audited once each week or month by an auditor or official of the post office department. Each clerk in the telegraph office has his separate cash drawer which opens automatically, when it is operated, and each one has a distinct sounding bell. When the clerk goes off duty he locks his cash drawer and in this way is fully protected. The machine is electrically operated and four small electric globes light up each time the machine is used.

Cheap Night Telegrams in England.—On January 1 cheap night telegrams were introduced experimentally on the British telegraph lines between London and Aberdeen, Scotland, and London and Belfast, Ireland. The charge is twelve cents for thirty-six words and one cent for every three words thereafter. The telegrams are accepted up to midnight at the head offices and delivered with the first morning delivery of letters.

Boston Aid Society Ball.—The twenty-seventh annual ball of the Telegraphers' Mutual Aid Association of Boston, Mass., was held on the evening of January 26, and was a great success in all respects. There was a large attendance and a substantial sum was turned in to the treasury of the association as a result of this affair. It is gratifying to note that the Boston association is so well supported. Everyone present had an enjoyable time.

T. M. B. A. Assessment.—Assessment 534 has been levied by the Telegrapher's Mutual Benefit Association to meet the claims arising from the deaths of William P. Phelps at Merchantville, N. J.; Julian S. Eves at Philadelphia, Pa.; Thomas J. Stout at Bonners Springs, Kan.; William H. Dale at Petrolea, Ont., and William W. Burhans at Washington, D. C.

LETTERS FROM OUR AGENTS.

PHILADELPHIA POSTAL.

Among recent visitors at this office were Mr. Charles P. Bruch, third vice-president, and Mr. L. Lemon, division superintendent, of New York, and Mr. R. A. Barton, manager at Lancaster, Pa.

Mr. J. O. Carr of the Morkrum Printing Telegraph Company, Chicago, is here and has installed a new printer between Philadelphia and New York.

Sympathy was extended to night chief operator E. H. Locke on the recent death of his brother.

The Lamson carrier system has been installed and business now moves more rapidly from the south to the north ends of the room.

The Telegraphers' Mutual Benefit Association, 195 Broadway, New York, has for nearly half a century proclaimed the absolute necessity of life insurance and provided a safe and economical form of protection for the home and family within the means of every telegraph and telephone employe. A certificate of membership affording protection of $500 or $1,000, or both, is easily obtainable by every one in good health engaged in telegraph or telephone service, either commercial or railroad, between the ages of 18 and 45, and should be held by all employes not otherwise provided with adequate life protection.

TELEPHONE ENGINEER with three years' experience with telephone dispatching systems, desires change. Best references. Also experienced in multiplex and simplex work. Address Engineer, care TELEGRAPH AND TELEPHONE AGE, New York.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

A Hint to Students—Some Things They Must Unlearn.

Did it ever occur to the student of electricity by the way of the old conventional text-book route that there are today many things he reads therein that he must unlearn, so to speak? If not, he should be cautioned at the start against accepting every explanation given as being literally true.

Many of the terms used and the explanations advanced are fanciful, to say the least, but necessary in order to convey certain ideas conforming to certain theories, and which latter in turn are apparently simply one big guess.

Probably the most fanciful theory advanced is that which tells us that the earth acting in the capacity of a return wire actually conveys an underground current of electricity between two widely separated localities in volume exactly equal to that which flows through the overhead wire connecting such localities. Nearly every text-book even goes so far as to show by means of dotted lines the course of the current through the earth. In some text-books this statement is given as an absolute fact, without any qualification whatever.

How much better it would have been to have stated that in the case of grounded circuits the earth connection gives the same result in the overhead circuit as would be obtained by a metallic return wire possessing no resistance. Obviously some law of compensation exists which enables us to utilize the earth in place of a return wire, but just what it is, is still an enigma. However, the earth affords a very convenient means of providing the other half of a circuit between both poles of the batteries, for which the draughtsman should be very thankful; otherwise where else could he have placed the dotted lines?

Text-books also tell us of the existence of earth currents, giving the student the idea that electric currents do actually flow through the soil itself. Now who ever measured or even detected a current while it was actually in the ground? Every indication of the presence of electricity in that form that the writer has heard of was invariably manifested, not in the earth or soil itself, but in the overhead conductors connecting two separated localities, and in which circuit the ammeter was connected. They are called earth currents, not because they actually flow through the soil, but because the earth's magnetic potential when raised to a greater degree at one locality than at another, owing to storms, sun spots, and other external influences, is capable of causing an electric current to flow through any good overhead conductor connecting such localities. Hence an earth current is one created by natural electricity in contradistinction to one created by the difference of potential in a battery or generator. The current, however, flows above ground, not through it.

The two-fluid theory, at one time quite generally accepted and advanced to explain the existence of the two polarities of current, is still given in many elementary text-books. It assumes that the current consists of two equal parts, each of which flows in an opposite direction from that of its companion, one being called positive and the other negative. The latest theory on this subject is that positive and negative electricity are one and the same thing, the terms merely relating to the direction or excess of one over the other.

Text-books are also full of such expressions as current, current volume, current density, current flow, etc., etc., the natural inference of which is that electricity is something tangible and therefore capable of being measured as we measure a material substance. Such impressions are misleading and must later be corrected, or at least qualified.

Electricity, according to our best informed authorities, is not a material substance. The longest conductor or coil of wire will not weigh one iota more when fully charged with electricity than it did before being electrified.

The student should early understand that the nature of electricity is unknown and that the name is merely a word adopted to designate that mysterious

Digitized by Google

force which is fast supplanting nearly all its competitors.

The terms current, volume, density, direction, etc., are simply arbitrary terms adopted to fit the different manifestations of this force, which are now believed to be the effects of different degrees of activity and actions of ether excitation. At this point the definition of electricity ends; no one can go further.

In the July 1, 1911, issue of this journal, Dr. C. P. Steinmetz, one of the leading electricians of the day, has called particular attention to the fallacy of many early theories still adhered to and actually taught in our public schools. It would be worth while for students to get a copy and read what he says about lightning, conductors, etc.

Personal.

Mr. G. K. Heyer of the Western Electric Co., New York, has returned from a general business trip in the South.

Mr. Frank F. Fowle, Chicago, Ill., a well-known electrical engineer and writer on telegraph and telephone subjects, has joined the editorial staff of the *Electrical World*, New York.

Mr. Frank S. Schanher, of Mount Clemens, Mich., son of the former manager of the Western Union office at that point, and an operator himself, sailed from New York for Egypt on February 8 to be absent about three months.

Count Wm. E. L. de la Motte, who was for thirty-eight years manager of the marine observatory of the Western Union Telegraph Company at Sandy Hook, N. J., now retired, was a New York visitor February 2, and called on many of his old friends.

Mr. Thomas A. Edison celebrated his sixty-fifth birthday on February 11 by abstaining from work. In the evening he and Mrs. Edison gave a dinner and reception at their home in Llewellyn Park, West Orange, N. J.

Mr. Patrick B. Delany, the well-known old-time telegrapher and inventor, has been named a delegate to the seventh annual convention and dinner of the Navy League of the United States to be held in Washington, D. C., February 22, 23 and 24.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. C. H. Mackay, president of this company, who has been absent from the city for some time past, is again at his desk.

The boy scouts of Roslyn, L. I., visited the office of president Clarence H. Mackay on February 10 under the command of Scout-Master Peach.

Mr. W. I. Capen, general superintendent of plant, was elected fourth vice-president of this company at a meeting of the Board of Directors on February 1.

Mr. E. B. Pillsbury, general superintendent, New York, who is spending a three weeks' vacation in the West Indies, has been visiting Havana, Cuba. During his absence Mr. L. Lemon, division superintendent, New York, is acting as general superintendent.

Mr. Edgar W. Collins has been appointed general superintendent of the Western Division, vice Mr. Guy E. Paine, who has been appointed superintendent of the second district, Western Division, with headquarters in Chicago.

The general and district superintendents of this company will meet in conferences in New York during March and April, as follows: Eastern Division, March 4, 5 and 6; Western Division, March 12, 13 and 14; Southern Division, March 26, 27 and 28; Pacific Division, April 22, 23 and 24.

Mr. C. H. Ashburn, district superintendent, Atlanta, Ga., came to New York recently to visit his son who is ill. After calling on a few friends, Mr. Ashburn returned to Atlanta, accompanied by Mrs. Ashburn, who has been a New York visitor.

Mr. W. W. Morrison, manager of the Lincoln, Neb., office of this company, has been transferred to the managership of the Mackay Telegraph and Cable Company, at Oklahoma City, Okla., vice W. A. Logan, resigned.

The Serial Building Loan and Savings Institution of 195 Broadway, New York, has opened an office at 253 Broadway to accommodate its patrons in the Postal Company's service.

This company is stringing four copper wires between Chicago, Ill., and South Bend, Ind., under contract with the South Bend Independent Telephone Company.

Wireless Telegrams for European Steamers.—Wireless telegrams are now accepted by the Postal Telegraph-Cable Company for transmission via Cape Race, N. F., the year round, but delivery to outbound steamers is not guaranteed between January 20 and August 20.

E. W. Collins, General Superintendent, Postal Telegraph-Cable Company, Chicago.

Mr. Edgar W. Collins, district superintendent of the Postal Telegraph-Cable Company at Cleveland, Ohio, who was promoted on February 1 to be general superintendent, with headquarters at Chicago, Ill., was born near Ottawa, Ont., on December 25, 1852. He entered the telegraph service in 1869, and in 1875 was employed by the Western Union at Cleveland, Ohio. In July, 1883, he was appointed

E. W. COLLINS,
General Superintendent, Postal Telegraph-Cable Company, Chicago.

chief operator of the American Rapid Telegraph Company, afterwards the Bankers' & Merchants', and when the Postal Company absorbed the Bankers' & Merchants', Mr. Collins became a Postal man and has been one ever since. He was afterwards manager of the Cleveland office, and in 1901 was appointed district superintendent at Cincinnati, Ohio, his headquarters being removed to Cleveland later.

Mr. Collins is a man of brilliant attainments, and, while a faithful company man, he is not unmindful of the interests of the employes under his charge, and is very popular among them.

Money Transfers for Switzerland. — Arrangements have been made by the Postal Telegraph-Cable Company with the Swiss Postal Administration for remitting money via the Deutsche Atlantische Telegraphengesellschaft (German Cable Company) to all points in Switzerland.

Hardships of Linemen in the Northwest. — Telegraph linemen in the Northwest meet with many hardships in the prosecution of their work during the winter. George W. Hall and William J. Wolf, linemen of the Postal Telegraph-Cable Company, were lost for three days in the deep snow on the summit of the Cascade Mountains in Washington, and were without food all that time. A searching party found them and brought them back to Easton, Wash.

Shooting Off Tree Limbs from Wires.—In order to clear a Postal wire of contact with the limb of a large tree at Canyonville, Ore., the lineman shot the limb off with his rifle. The tree was too large to climb.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

A contract has been closed between this company and the Underwood Typewriter Company, New York, for the delivery of 5,595 typewriters for use in Western Union offices throughout the country. The company has an option to increase this order up to 10,000 machines during the next five years. The first lot of 1,000 machines will be delivered in two months and thereafter they will be delivered in lots of 750. The machines will be arranged with a special keyboard. There will be no small or "lower case" letters, all the letters being Gothic capitals. Mr. H. E. Roberts, general purchasing agent, New York, will have charge of the distribution of the machines.

Mr. E. M. Mulford, division commercial superintendent, New York, has returned from a business trip through the South. He made a short trip to Havana in company with Mr. T. W. Carroll, of New York, assistant to the general manger, who has also returned.

Mr. W. E. Athearn, engineer of equipment, New York, has gone on a trip through the South on company business.

Mr. S. M. Williams, manager of press service, New York, will make an address before the New York Telephone Society at the regular meeting on February 20.

Mr. E. E. Williams, district superintendent, has been appointed special agent for the Southern Division, with headquarters at Atlanta, Ga., and Mr. J. E. Schofield has been appointed acting district superintendent at the same point in place of Mr. Williams.

Mr. J. F. Nathan, commercial superintendent, New York, has issued a circular letter dated January 30, announcing to the public the inauguration of the new classes of cable service, including cable letters, week-end cable letters and deferred service. These new services have been fully described in recent issues of this journal.

Mr. A. C. Kaufman, commercial agent, is all ready at work in planning the arrangements for telegraphic facilities at the Democratic National Convention to be held in Baltimore, Md., next June. Two hundred wires and one hundred extra operators will be available to handle the business, which promises to be unusually large.

Mr. Edward Altemus, supervisor of messengers, Greater New York district, has resigned. After a rest he will go to California.

Mr. R. L. Smith, of the Selma, Ala., office has been promoted to be assistant manager at Charlotte, N. C.

Miss M. E. Davis, formerly located at Washington, D. C., has been appointed night manager at the new Vanderbilt Hotel, New York.

Digitized by Google

This company will, on March 1, begin demolishing the buildings at Nos. 14 and 18 Dey Street, New York, at the rear of 195 Broadway, preparatory to the erection of a 26-story structure which will have an extension running to Fulton Street. When this section is completed the annex to the main building, at 10 and 12 Dey Street, will be torn down and rebuilt to the height of twenty-six stories. Later, the main building itself, at 195 Broadway, will likewise furnish a site for a similar extension, thus completing a structure which will have a frontage of 75 feet on Broadway, 250 feet on Dey Street and 33 feet on Fulton Street. The subsidiary concerns which will be displaced by the reconstruction have been provided for in adjacent buildings. The first unit of the new building will be ready for occupancy by May, 1913. The completed building will represent an outlay of about $3,000,000.

Two floors and parts of two other floors in the Riker Building, at the corner of Broadway and Dey Street, opposite 195 Broadway, have been leased by this company and several offices are being moved from 195 to the new quarters. These changes include the offices of Mr. W. A. Sawyer, district commercial superintendent; Mr. H. E. Roberts, general purchasing agent; Mr. J. W. Rahde, auditor of the Eastern Division; Mr. Herbert Smith, district traffic superintendent; Mr. F. N. Whitney, tax attorney; Mr. J. McRobie, general manager, American District Telegraph Company of New Jersey, and Mr. McLane, auditor of the same company. The bookkeeping department, the Gold and Stock Telegraph Company's quarters, the underground cablemen's and the tube-repairing departments are being moved to 170 Fulton Street. The offices on the third floor vacated by district commercial superintendent W. A. Sawyer will be taken by the Associated Press.

The New York Telephone Company has moved its office into the Western Union quarters at Goshen, N. Y., and Miss Ruby Thompson, formerly manager of the Western Union office at Calicoon, N. Y., has been appointed resident manager for the telephone company at Goshen, and will have charge of the interests of both companies. Mr. John Kearney, manager of the Western Union at Hoosick Falls, N. Y., has been appointed manager of the joint interests at that point, the telegraph office having been moved in the new quarters of the telephone company. Mr. E. R. McCreedy, Western Union manager at Greenwich, N. Y., has been appointed resident manager at that point for the joint interests. Miss H. M. Burbank, manager of the Western Union at Hudson Falls, N. Y., has been appointed resident manager of the telephone company and will have charge of the joint interests at that point where the telephone company recently moved its quarters into the Western Union office. The Western Union office at Fishkill, N. Y., has been moved into the new telephone building at that place and the joint interests placed in charge of Mr. C. J. Shanon, former manager for the Western Union, who is now resident manager for the telephone company.

Mr. C. R. Tyler, an old-time telegrapher, now one of the street railway magnates of Omaha, Neb., was a recent New York visitor en route to Florida. In 1868 Mr. Tyler was day operator at Pine Bluff, Neb., when Mr. Theo. N. Vail was night operator at the same point. Mr. Vail, hearing of Mr. Tyler's presence in the city, entertained him at dinner, together with Messrs. F. D. Giles and John Morison of the Western Union staff at 195 Broadway, who were also associates of Messrs. Tyler and Vail in the late sixties. The gathering of these four old friends at the dinner table in the Railroad Club was a very happy occasion and old-time telegraphic reminiscences were recounted.

Mr. Raymond D. Gould, recently appointed manager of the Western Union Telegraph Company at Houston, Tex., was born in St. Charles, Mich., February 13, 1876. He began his telegraphic career at Owosso, Mich., in 1892, and until 1898 worked for the Postal, and the Western Union companies, and the Norfolk & Western Railway. Between 1898 and 1899 he was manager of the Western Union office at Leadville, Col., and for nine years afterwards was employed as operator on the leased wires of the Associated Press at various points. He returned to the Western Union service as district commercial agent at Dallas, Tex., in 1910, and became manager at El Paso, April 18, 1911, whence he was transferred to Houston.

Mr. Donald A. MacLaine, recently appointed traffic chief and supervisor of the Western Union cable station at Bay Roberts, N. F., was born in Liverpool, England, December 14, 1857. He began receiving instruction in telegraphy at Liverpool in 1870 and became an operator in January, 1871. He remained in the service of the post office telegraphs in that city until December, 1875; when he went to the Ballinskelligs office of the Direct United States Cable Company. In 1879 he went to St. Pierre Miquelon as a mirror operator for the French Cable Company and in 1881 he joined the American Telegraph & Cable Company's force at Canso, N. S. In August, 1910, he went to Bay Roberts and installed the plant there for the operation of the new Western Union cable after which he received his recent appointment.

Morse Electric Club Dinner.

The annual dinner of the Morse Electric Club, which will be held at the Hotel Savoy, Fifth Avenue and Fifty-ninth Street, New York, Saturday evening, February 17, promises to be one of unusual interest and will be attended by prominent telegraph and telephone officials and other invited guests. Mr. Theo. N. Vail, president of the Western Union Telegraph Company and of the American Telephone & Telegraph Company, will be the guest of honor. Other invited guests are Messrs. N. C. Kingsbury, vice-president American Telephone & Telegraph Com-

Digitized by Google

pany; Union N. Bethell, president New York Telephone Company; F. H. Bethell, president Bell Telephone Company of Pennsylvania; W. C. Brown, president New York Central Lines, E. T. Jeffery, president Denver & Rio Grande Railroad Company, and Judge Victor J. Dowling, all of New York.

Transformers are being installed along this company's lines paralleling the single-phase trolley road between Chicago, Ill., and South Bend, Ind., for the purpose of correcting the inductive effects of the trolley line.

The Cable.

Mr. G. G. Ward, vice-president and general manager of the Commercial Cable Company, New York, has been absent several weeks on account of illness. He is now convalescing.

Mr. P. H. Burns, electrical engineer to the Bahamas Government, Nassau, N. P., has resumed his duties after a vacation of six months. The twentieth anniversary of the installation of the Bahamas cable to Florida occurred on February 3.

Capt. W. G. S. De Carteret, of Halifax, N. S., commander of the cable steamer "Minia," of the Anglo-American Telegraph Company, was a recent visitor in New York.

A wireless message from the Commercial Cable Company's repair steamer "Mackay-Bennett" on February 10 announced the capsizing of the three-masted schooner "Caledonia," which she had in tow, by the weight of ice in the rigging. The crew of the schooner were rescued. The "Mackay-Bennett" was operating east of Halifax, N. S., at the time.

Mr. J. H. Carson, manager of the Anglo-American Telegraph Company, London, England, arrived in New York on the steamer *Oceanic* February 8. Mr. Carson's visit to this country is one of business connected with the cable service.

Mr. Carson is one of the pioneers of the cable service which he entered in 1852. In 1865 he joined the then newly-formed Atlantic Telegraph Company, which in the year following became the Anglo-American Telegraph Company. He was appointed manager of the company in 1893, and still remains with it. Mr. Carson has an intimate knowledge of all matters pertaining to transatlantic telegraphy, his forte being the rapid handling and transmission of messages, in which he has made some remarkable records. He represented the Anglo company as delegate to the International Telegraph Conference in Budapest, Hungary, in 1895, and at the London Conference in 1903.

Deferred Cable Messages. — The proper place for the letters LCF, LCO or LCD in deferred plain language cable messages, as announced by the Commercial Cable Company, is before the cable address or before the name of the addressee.

Reduction of Press Rates to South Africa.— The Eastern Telegraph Company, London, has agreed to reduce the press rate from England to South Africa from eighteen cents to seven cents per word, on condition that such messages shall be dispatched after ordinary and deferred telegrams.

Commercial Pacific Cable Interrupted.—The cable of the Commercial Pacific Cable Company, in the Midway-Guam section, is interrupted, probably close to the Midway Station. That station reported tremendous seas breaking on the reefs for several days. Messages for Guam, Dutch Indies, the Philippines, Hong Kong, Macao, Corea, China and Japan can, during this interruption, only go by the Atlantic cable routes.

The Telephone.

Mr. U. N. Bethell, president of the New York Telephone Company, has been elected a director of the Liberty National Bank, New York.

New Telephone Exchange in London.—The postoffice has opened a new central-battery telephone exchange in Creechurch Lane, London. The switchboard, which is of the forty-volt type, has accommodations for 9,000 subscribers.

Transatlantic Telephony.—Prof. M. I. Pupin states that transatlantic telephony would be practicable by the use of loading coils. A different type of cable from the present would have to be made, however. The problem is a commercial one rather than one of engineering.

Telephony Between England and Holland.—Direct telephone communication between London, England and Amsterdam and Rotterdam, Holland, took place on February 1. As soon as negotiations with the French and Swiss administrations have been completed the British postmaster general expects to open telephone service between England and Switzerland.

Cumberland Bell Bond Issue. — The stockholders of the Cumberland Telephone & Telegraph Company at the annual meeting in Louisville, Ky., on February 1, voted a bond issue of $15,000,000 for improvements and extensions. Messrs. W. T. Gentry and J. Epps Brown, president and vice-president and general manager, respectively, of the Southern Bell Telephone Company, Atlanta, Ga., and Mr. U. N. Bethell, of New York, vice-president of the American Telephone & Telegraph Company, were elected directors.

Taxing Telephones in Philadelphia.—Alderman Morris E. Conn, of Philadelphia, has introduced an ordinance imposing a license fee or tax of $5 on each telephone installed after May 1. The chief of the Electrical Bureau is empowered to investigate complaints regarding telephone service for which a fee of $1 will be charged, payable by the company. Failure to correct faults entails another tax of $5 per month and other taxes of $5 are to be imposed for sins of omission and commission. If the ordinance becomes law the telephone companies will find it rather difficult to keep on the straight and narrow path.

Digitized by Google

Telephone Pioneers.—A meeting of the executive committee of the Telephone Pioneers of America was held in New York, February 9, at which Messrs. J. J. Carty, Thos. D. Lockwood, Thos. B. Doolittle, Charles R. Truex and Henry W. Pope were present. Dr. Alexander Graham Bell was unanimously elected an honorary member. The secretary was authorized to present to president Theo. N. Vail, of the American Telephone & Telegraph Company, a group picture of the pioneers suitably framed and with an inscribed plate. Action on the selection of a place for the next meeting was deferred.

The Randall Telephone Repeater.

The *Boston Sunday Post* of February 4 contained an illustrated article on the telephone transmitter and repeater of Mr. Charles Adams-Randall, both of which devices we described on page 215 of our issue for March 16, 1911.

Mr. Randall states that these instruments have solved the problem of long distance telephone transmission. Tests were made at the convention in Chicago last year of the National Independent Telephone Association and it is said a deep impression was made upon the delegates as to the possibilities of the instruments for long distance work.

Mr. Randall claims that the transmission of voice currents between Boston and San Francisco is practicable with his high power transmitters and one of his repeaters every 1,000 miles.

Radio-Telegraphy.

Mr. Guglielmo Marconi and Mr. Godfrey C. Isaacs, managing director of the Marconi Wireless Telegraph Company, London, are expected to arrive in the United States during March.

All-English Wireless Service.—It is reported from London that negotiations are being conducted between the British government and the Marconi Company with a view to establishing wireless service between all of the British dominions throughout the world.

Bicycle Wireless Outfit.—It is stated that Mr. I. Wolff of Cambridge, Mass., has developed a wireless outfit for bicycles, which enables the rider to communicate with any other rider provided with receiving apparatus. He has thus communicated with an associate three-and-a-quarter miles distant.

Opening a New Wireless Station in Spain.—The new Marconi wireless station at Aranjuez, near Madrid, Spain, was formally opened on January 28 in the presence of the king and queen of Spain. Congratulatory dispatches were exchanged with the English and Italian monarchs, and a message was received direct from Canada conveying the good wishes of the Canadian prime minister.

It is stated that a special license good for the opening day only was granted by the British Government permitting the Poldhu station to receive messages from the new Aranjuez station to be transmitted to America.

Private Wireless Plant in Canada.—The Goodyear Tire & Rubber Company of Canada operates a wireless system between its offices in Toronto and its factory at Bowmanville, Ont., using private apparatus. A large business is handled between the two points. Mr. Fred B. Barton is in charge of the Toronto station.

Marconi Company to Absorb United Wireless.—Negotiations it is stated are under way for the absorption of the United Wireless Telegraph Company by the Marconi Wireless Telegraph Company, of London. The United Wireless Company is now in the hands of receivers after having been financially wrecked by Col. Christopher C. Wilson and his associates who are now in jail.

Day Wireless from Honolulu to Washington.—Wireless communication was had on February 2 between Admiral Thomas, commander of the naval fleet at Honolulu, Hawaii, and Washington, by way of the Mare Island, Cal., Navy Yard and the Key West, Fla., stations. The transmission was effected in daylight over distances of 2,098 miles from Honolulu to Mare Island, 2,205 miles from Mare Island to Key West and thence to Washington.

The London Radio-Telegraph Conference.

The Marconi Wireless Telegraph Company, New York, has issued a statement with reference to the radio-telegraph conference to be held in London, June 4.

The whole convention, it states, is based on the fact that telegraph lines are owned by governments and is absolutely inapplicable to the United States where the lines are owned by corporations which are not parties to the Convention.

"Article 1 is against the established principles of the American people to impose restrictions on private enterprises lawfully carrying on legitimate business and such restriction will hinder and impede the progress of the art of wireless telegraphy.

"Article 3—It is highly improper and unjust to throw open for the use of the whole public and to vessels equipped with any system or equipped in any cheap way stations on land which have been established and worked up to their present efficiency by the expenditure of large amounts of money and the exercise of intelligence and brain power.

"Article 5—Can only apply to nations which control the land lines, the United States can only request land line companies to connect or connections will only be made if remunerative business is shown.

"Article 7—By this article working may be altogether prescribed at the option of the Government; this is too sweeping.

"Article 9—A tariff per word pure and simple cannot be adopted in the United States until the land line companies agree to establish a word rate."

Canadian Notes.

Mr. Donald Coons, whose appointment as superintendent of telegraphs, Alberta division, Canadian Pacific Railway, at Calgary, Alb., was announced in our issue for January 16, was born at Iroquois, Ontario, October 25, 1870. He began his telegraphic career at Swift Current, Sask., in 1894, and has filled various important positions in the telegraph service throughout the northwestern territory of the Dominion, his last previous position being that of inspector of telegraphs. Mr. Coons has had a wide experience, which will find abundant application in his new post.

Mr. Daniel H. Bowen, whose appointment as assistant superintendent of telegraphs, Ontario division, Canadian Pacific Railway, was announced in these columns January 16, is a Canadian by birth and his business career has been spent entirely in his native land. He was born in Culloden, Ontario, May 7, 1866, and entered the telegraph service on the Canada Southern Railway at St. Thomas, Ont., in August, 1881, which position he held until October 1, 1886. He then accepted a position as agent for the Canadian Pacific Railway Telegraphs at St. Thomas, Ont., and in April, 1890, became local manager for the same interests at London, Ont. On January 1 of this year he was promoted to his present position.

New Telephone and Telegraph Construction on the Canadian Pacific.

Mr. W. J. Camp, assistant manager, Canadian Pacific Railway Company's telegraph, Montreal, Que., informs us that the president of that company has authorized appropriations for the following telephone train-dispatching circuits in addition to about four thousand miles already equipped: Kamloops to North Bend, B. C., 121 miles; North Bend to Vancouver, B. C., 129 miles; Medicine Hat to Lethbridge, Alta., 116 miles; Moose Jaw, Sask., to North Portal, Sask., 167 miles; Guelph Junction, Goderich & Listowell branch, Ont., 112 miles; Grand Mere & St. Gabriel branch, Que., 56 miles., which will make a grand total of 4,700 miles of telephone train dispatching on the Canadian Pacific Railway.

Authority has also been given for the erection of additional copper wires, as follows: Canso, N. S., to Montreal, Que.; Montreal, Que., to Winnipeg, Man.; Winnipeg, Man., to Moose Jaw, Sask.; Saskatoon, Sask., to Calgary, Alta., via Edmonton, besides several shorter circuits, making a total of about 6,000 miles of new wire.

Authority has also been given for considerable reconstruction of various parts of the line in order that the telegraph system shall be kept up to its present high standard. There will also be telegraph lines built along new branches of the railway to be constructed during the coming season.

The Reid Monument

The committee formed for the purpose of considering the question of erecting a monument or other suitable memorial to the late James Douglas Reid met at 253 Broadway, New York, on the call of Mr. C. P. Bruch, president of the Magnetic Club, on February 14, for the purpose of (1) to organize the committee; (2) to determine whether or not a monument or memorial shall be erected; (3) to devise ways and means of raising necessary funds, if it is decided to erect such monument or memorial.

In issuing the call, President Bruch said:

"At a meeting of the Magnetic Club held in New York November 15, 1911, attention was called to the fact that the grave of Mr. J. D. Reid, in Rochester, N. Y., is marked only by a very simple stone. It was pointed out that Mr. Reid was the first superintendent of telegraph; the employer of many boys who in later years attained success and prominence in the telegraph and other lines of business; the first employer of women in the telegraph service; the friend and contemporary of Morse; one of the organizers and the first president of the Telegraphers' Mutual Benefit Association; one of the organizers of the Old-Time Telegraphers' and Historical Association; that he was actively interested in and identified with other organizations and movements for the benefit of telegraphers; the author of the only history of the telegraph as yet published, and the founder and editor of the first electrical paper in the world.

"It was suggested that his services to the telegraph, his friendship for telegraphers, his helpfulness to everyone, and his gentle, lovable character—endearing him to everyone who knew him—entitles him to a more suitable and lasting monument than now marks his grave, and the opinion was expressed that it is the duty of telegraph associations and of the telegraph fraternity at large, to co-operate in erecting a monument to him.

"Pursuant to this suggestion, the Magnetic Club directed its officers to communicate with the various telegraph associations, requesting their co-operation in a movement to raise the necessary funds and erect a suitable monument or other form of memorial and to designate members to serve upon a committee to take charge of the movement.

"Attached is a complete list of the gentlemen who have been designated by their respective associations to serve upon such committee."

Telegraphers' Mutual Benefit Association. Michael J. O'Leary, W. C. Humstone.

Old-Time Telegraphers' and Historical Association: F. J. Scherrer, J. B. Taltavall.

The Society of the United States Military Telegraph Corps: David Homer Bates, Charles A. Tinker.

Association of Railway Telegraph Superintendents: L. B. Foley, F. G. Sherman, E. P. Griffith.

Magnetic Club, New York: C. P. Bruch, A. B. Chandler, W. B. Dunn.

Serial Building Loan & Savings Institution, New York: James R. Beard, Edwin F. Howell.

Gold and Stock Life Insurance Association, New York: Gardiner Irving, Louis Dresdner.

New York Telegraphers' Aid Society: Thomas M. Brennan, Robert J. Marrin.

The Morse Club, New York: William J. Dealy, William Holmes.

Postal Telegraph Club of Atlanta, Atlanta, Ga.: G. H. Usher, W. C. Daviet.

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. There is a general demand for knowledge on the quadruplex, duplex, etc., and to aid in the acquirement of such knowledge we are extending our help to students by asking questions on these subjects in each issue of our journal, so that they may be encouraged in their studies by answering them. We use as our textbook Maver and Davis' "The Quadruplex," and students should have a copy of this book at hand in order to be able to give the answers. The questions are progressive and a careful reading of the book on the points under inquiry unfolds the answers. This method of acquiring technical knowledge is a fascinating one.]

WHEATSTONE SYSTEM (*Concluded*).

How much play is allowed for the armatures of the polarized relays?

Why is it necessary to limit the play of the armatures of these relays?

What is the effect of high speeds on the operation of the sounder?

On what class of circuit may the Wheatstone system be operated?

On what system is it operated by the Western Union Company?

What is the capacity of a circuit operating the Wheatstone system duplex?

What changes are necessary in order to balance a Wheatstone duplex, and how are they effected?

How is a balance obtained on a Wheatstone duplex? Does it differ from the method of balancing a quadruplex?

The polar relay being inaccessible, how is a balance indicated?

Trace and study the connections in Fig. 63.

What advantage is gained by interposing the resistance R between the rocker arm of the transmitter and the switch?

Why was the polechanging key displaced in this country by the pole changer?

What power is used to operate the perforating punches?

Study the construction of the perforators.

What air pressure is used for punching the tape?

Describe the various operations through which a message must pass in transmission and reception.

How many hands does a message pass through in the Wheatstone system as compared with the Morse?

What makes the Wheatstone system of special advantage on press circuits in England?

Why is the Wheatstone system particularly serviceable when wires are prostrated by storms?

Bound Volumes of Telegraph and Telephone Age.

TELEGRAPH AND TELEPHONE AGE for 1911 covers a period of great activity in telegraph and telephone development and contains a complete record of all important events in these lines, besides much other interesting and valuable matter of general and technical interest. The volume is well worth preserving by students and subscribers, as its contents will be frequently referred to on account of their important character.

Bound volumes are now for sale at the publication office of this journal, 253 Broadway, New York, at $3.50 per volume, express charges collect. These volumes are neatly bound in cloth and will be found very handy for the library.

The New Western Union Office at Winnemucca, Nev.

A general reference was made in our issue for January 16 to the new office of the Western Union Telegraph Company at Winnemucca, Nev. We have since received a detailed account of the office equipment, which will be found of general interest.

The office, to some extent, supplants that at Reno, Nev., which has for a decade or more repeatered all of the important circuits east and west on the Central route.

The new office is complete in every detail and represents the latest in modern practice. All of the multiplex equipment, consisting of nine direct-point duplex repeaters, three quadruplex sets and two printed repeaters, all of the new bridge type, are assembled on standard repeater tables. The office has been provided with the latest standard equipment for obtaining maximum results from the facilities, including distributing frames, bridge test sets, volt mil-ammeters, Gill selectors, etc.

The battery plant consists of 620 cells of chloride accumulators, manufactured by the Electric Storage Battery Company of Philadelphia, for the main potentials, divided into banks of forty cells each, type E. T. for the first and second potentials and type C. T. for the third and fourth potentials, and two banks of 39 cells each, for locals. The main potentials are charged in multiple and discharged in series. The locals are charged in series and discharged in multiple. The battery is charged from the latest type of mercury arc rectifier, manufactured by the General Electric Company. The charging current is obtained from the electric lighting service, and the power is rather unique in character, consisting of gasoline, steam and water, the source of the latter being from the snow in the mountains and after giving up its potential energy, is stored in a reservoir for domestic use of the city's population. The necessary rheostats, switches, meters, etc., used in connection with the operation of the battery, are mounted on a slate panel, manufactured by the Electric Railway & Supply Co. of San Francisco. This panel, together with the rectifier, distributing frames, switch and loop boards, repeater and operating tables, were located with a view to easy communication and the minimum travel for equipment attendants.

All of the equipment was assembled and installed by the Western Union district equipment department, of which Mr. A. W. Douglas is supervisor.

Classification of Western Union Offices.

The following definition of the various classes of Western Union offices has been officially announced:

Class 1. Western Union Independent Office:—An office, representing a distinct unit in the service, operated by the Western Union Telegraph Company, and having its business checked direct by other offices. Messages transmitted directly over telegraph lines, except during closed hours, when telephone toll lines may be used.

Class 2. Western Union Branch Office:—An office operated by the Western Union Telegraph Company, under the supervision of and in the same area as a Class 1 office and having its business reported and checked as of the office to which it reports.

Class 3. Western Union Tributary Office:—An office operated by the Western Union Telegraph Company under the supervision of a Class 1 office, but located in a separate area and having its business reported and checked as of the office to which it reports.

Class 4. Western Union Joint Railroad Office:—An office operated by a railroad company, representing a distinct unit in the service, and having its business checked direct by other offices.

Class 5. Western Union Branch Railroad Office:—An office operated by a railroad company, but located in a city or town in which there is also a Class 1 or Class 10 office, and having its business reported and checked as of the office to which it reports. Such offices are branches of Class 4 offices in exceptional cases only.

Class 10. Joint Check Direct Office:—An office located at a joint commercial or central office, operated by joint employes in the premises of the telephone company, and having its business checked direct by other offices. Offices which employ telegraph operators for the whole or part of each business day will be known as Class 10A, and offices which rely wholly upon telephone transmission to points of transfer will be known as Class 10B.

Class 11. Joint Tributary Office:—An office located at a joint commercial or central office, operated by the joint employes in the premises of the telephone company, and having its business reported and checked as of the Class 1 or Class 10 office to which it reports. Classes 11A and 11B defined as under Class 10.

Class 12. Joint Toll Agency:—An office operated by a joint agent of the telephone and telegraph companies, located at a coin box or non-coin box toll station or commission exchange, and having its business reported and checked as of the Class 1 or Class 10 office to which it reports. Messages are transmitted over telephone toll lines.

Class 13. Joint Public Station, Company Attended:—A local public station operated jointly with the telephone company, and having its business reported and checked as of the Class 1 or Class 10 office to which it reports.

Class 14. Joint Public Station, Agent Attended:—A coin or non-coin box local public station operated by a joint agent, and having its business reported and checked as of the Class 1 or Class 10 office to which it reports.

At all of these offices, classes 1 to 14, inclusive, direct telegraph rates will apply and written messages will be received.

Class 15. Joint Public Station, Agent Attended: A coin or non-coin box local public station operated by a joint agent, and having its business reported and checked as of the Class 1 or Class 10 office to which it reports. The usual local exchange telephone charge will be made for connection with the telegraph office in addition to the telegraph charges, and the agent will not be required to accept written messages.

Reminiscences of Early Telegraph Days in New York State.

Mr. W. D. Hanchette, an old-time telegrapher, is the author of an interesting article in the *Watertown* (N. Y.) *Times* under the title, "Reminiscences of a Veteran Telegrapher." He gives anecdotes of some of the old timers who are now well known in the business world, and the scene of his narrative is Watertown and vicinity. He states that Mr. Edwin Pope, who was superintendent of the northern New York division of the Montreal Telegraph Company in Watertown, was probably the first operator to copy press report by sound.

Other former telegraphers mentioned, all of whom began as messengers, are William Phillips, now of Reno, Nev., William and Charles Cundell, Matthew Hickey, Charles Ballard and several others who acquired prominence in and out of the telegraph business.

Western Union Electrical Club of St. Louis.

At a meeting of the Western Union Electrical Club of St. Louis held January 25 the following officers were elected: G. R. Alger, president; C. W. Frey, vice-president; A. Turner, secretary; Miss L. M. Hood, treasurer. The president announced the following Executive Board: E. A. McKnight, chairman; H. G. Gosting, W. J. Armstrong, W. J. Dill, E. H. Moore, J. J. McCruden, C. W. Crary.

In the absence of Prof. Hallet, the regular lecturer, the club listened to a very instructive address on and demonstration of apparatus and the uses of the Wheatstone bridge as applied to telegraph line testing, by Mr. E. A. McKnight, recently appointed senior assistant wire chief. It has been decided to alternate the lectures and demonstrations between the regular lecturer and any employe competent to discuss and demonstrate practical points in connection with the regular service.

Mr. Fred B. Barton, in charge of the Goodyear's Tire & Rubber Company's wireless station at Toronto, Ont., says, regarding the renewal of his subscription: "No wireless operator and engineer should be without TELEGRAPH AND TELEPHONE AGE."

The Chicago Western Union Office About 40 Years Ago.

BY L. K. WHITCOMB, DALLAS, TEX.

In March, 1873, the main office of the Western Union Telegraph Company in Chicago was located on the fifth floor of the Central Hotel on the corner of Market and Washington streets, having been removed from the Canal Street office across the river, the latter having been the temporary location after the great fire of 1871. There was but one telegraph company in the city, and there were less than sixty commercial operators employed. In May of that year the office was moved to the corner of La Salle and Washington streets, where it remained twenty years, when it was changed to its present location on the day of the opening of the World's Columbian Exposition, May 1, 1893. If I remember correctly, the room on the corner of La Salle and Washington streets was about sixty feet square, and it afforded space for all the operators, also the bookkeepers, batteries and storage. Two rows of operating tables on one side of the room provided ample space for the wires and two fifty-wire switchboards were only partially filled. The equipment was particularly up to date, there being included several "button" repeaters and three Stearns duplexes, the latter working with New York, Milwaukee and Cincinnati, respectively. There were less than fifteen branch offices at that time, including offices in railroad stations, and two wires handled all the city or "Metropolitan" business. The traffic of the entire Northwest (the Northern Pacific Railroad had not been built) was relayed at Milwaukee, and one duplex, usually worked by one operator, carried it. Between Chicago and New York one duplex and two single wires were used for messages, and one wire carried all the press. One wire on the Chicago and Northwestern Railroad was assigned to business for all points between Chicago and Omaha, and it was paralleled by the "overland" wire, which ended at Corrine, Utah, and handled the entire Pacific coast business, including the press. One wire on the Chicago, Burlington & Quincy route to Keokuk and another to Quincy, via Galesburg, provided for the business of that road, and the Iowa business was relayed at Burlington, one wire on the Chicago, Rock Island & Pacific to Omaha, Neb., one to Muscatine, Iowa, and two to Peoria, Ill., covered that territory; one on the Chicago & Alton Railroad to Springfield and one to St. Louis provided ample facilities. The St. Louis wire carried all the business for the Southwest, and, without going into further detail, one wire to a railroad was generally sufficient to carry the business with all towns through which it passed.

Perhaps a review of the personnel of the force and their assignments would better convey an adequate idea of the conditions than any other statement could. The following covers about all of them: F. C. Swain, manager (chief operator); George C. York, assistant manager; C. G. Sholes and H. W. Plum, chief operators; Wm. H. (Billy) McMillan, chief message clerk; Ed. Angel, timekeeper, and the following day operators: H. W. Hunt and Wm. Wallace, Jr., New York duplex; Charles H. Lithgow, New York; Curtis D. Meserve, Buffalo; E. L. Armstrong, Pittsburg; Dr. F. N. Benson, Indianapolis and Louisville; John L. Martin, Cincinnati; Charles T. Day, St. Louis; O. W. Hamilton, Springfield; J. Newton Crittenton, Milwaukee; Charles Wilkinson, Milwaukee; A. H. Babb, Quincy; H. E. Tatge, Burlington; Wm. H. Walsh, Davenport and way; Daniel Francis, Corrine, Utah; M. F. (Jeff.) Prentice, Peoria; Miss Lizzie Veazey, Dubuque; A. J. Long, Omaha; Elmer Stephens, Peoria way; Mrs. D. M. Tillotson, Illinois Central way; Fred M. Randolph, Fort Wayne way; L. J. Amsden, Lafayette way; Miss Julia Phelps, Michigan Central way; M. H. Smith, Eastern report; C. S. Jones, Chicago and Northwestern way. City department: C. W. Jones, chief; Ed. Bangs and Miss Lily Smithels, Board of Trade office; S. L. Robinson, manager; J. E. Pettit and D. S. Anderson, operators, the latter working at the main office, outside of 'change hours.

Night force: H. C. Maynard, manager; L. C. Springer, assistant manager; C. H. Kelly, wire chief; Octave Valliquet, late-night operator. Operators: A. J. Mereness, Milwaukee; C. F. Gooding, Milwaukee report; Douglass Burnett, New York report; H. J. Forman, "Smith" report; Gib. Merrill and George W. Hurd, New York duplex; Charles W. Thayer, Detroit; Dr. Bradnack, Buffalo; J. Q. Mason and Ed. Dorval, St. Louis, and overland alternate nights; E. G. Foote, Springfield; E. Lomasney, Burlington report; L. K. Whitcomb, Peoria and Dubuque report; M. L. Lawson, Springfield and Quincy report; Jno. M. Kemp, Omaha report; Francis W. Jones, Indianapolis; Wm. Linton, Cincinnati; E. O. Martin, Louisville; F. M. Lester, Pittsburg; George Wilkinson, L. W. Pitcher, Jerry O'Connell, way wires. Check boys: W. R. Halligan, A. J. Gallagher and George Shaw. There may be others who might rightfully claim place in this list, whose names are forgotten, but the above is about as I found them in the old "Market Street" office.

It would indeed be interesting to trace the careers of these operators, if such a thing were possible, as they scattered far and wide into various occupations; but time and space fail. As I look over the list, sixteen of them have signed their last pay check, and there is only one who has remained continuously in the service at Chicago. There are two or three others who are now employed there who worked in that office at the time. In those days there were no "woggle bugs" or other sending machines, the typewriter was not thought of as a telegraphic adjunct, and the working tools, other than those fastened to the tables, were a good pen, pencil or stylus.

Telegraphing was an art, proficiency in which depended on the mental and physical make-up of the operator, added to his experience and good judgment, without mechanical aids. The limited facilities and heavy business demanded ability of a high order. An operator was generally known by

Digitized by Google

the quality and speed of the "Morse" he sent, and the penmanship and correctness of his copy. An operator who had received "a prize package" was a sort of seven-day wonder, to be questioned and interviewed, over and over again, and to be called up on the "carpet," made the recipient of that honor (?), a sort of a hero. That there were first class operators in those days goes without saying. The quality of their work demonstrated the fact.

ANSWERS TO QUESTIONS.

[In this department questions on matters of a practical character, and of general interest, will be answered. Questions intended for this department must be signed by the writer's full name—not for publication, but for identity. No attention will be paid to anonymous communications.]

(87) Q. How are newspaper despatches transmitted by wireless across the Atlantic? Is there any special preparation or arrangement for handling this class of business? S. P. O.

A. No special preparation is made or necessary. The correspondent files his matter with the telegraph company as he would an ordinary telegram, and it is handled just as it would be by a wire company.

(88) Q. Knowing that TELEGRAPH AND TELEPHONE AGE always stands ready to aid a struggling student, I wish to ask for light upon some points which I could better understand if explained by some one who knows more than I do about electricity. Electrical books state that

(1) Resistance varies directly with the electromotive force and inversely with the current.

(2) Electromotive force varies directly with the resistance and with the current.

(3) Current varies directly with the electromotive force and inversely with the resistance.

Will you please express these facts in plainer language and give an example in each case?

R. A. W.

A. These statements are expressed algebraically thus:

$$(1)\ R = \frac{E}{I},$$

$$(2)\ E = R \times I,$$

$$(3)\ I = \frac{E}{R},$$

E representing electromotive force; I, current, and R, resistance.

In Case (1) let us assume that E = 50 and I = .5, the value of R therefore must be 100. Suppose now we change the value of E to 100, I remaining the same as before, we get 200 as the value of R. We have increased the E. M. F. to twice as much as it was, and as a consequence the resistance is also increased twice as much. That is what is meant by the statement that the resistance increases directly with the E. M. F.—it increases as the E. M. F. increases and decreases as the E. M. F. decreases.

If we now decrease the value of the current, I, one-half, making it .25 instead of .5, the value of the E. M. F. remaining at 50, we obtain 200 as the value of R. If on the other hand we increase the current twice as much, making I = .10, we get 50 as the value of R. This shows that by decreasing the current we increase the resistance in the same ratio, and by increasing the current we decrease the resistance. That is what is meant by the statement that the resistance varies inversely as the current—that is, one increases in "inverse proportion" as the other decreases, and *vice versa*.

The same reasoning applies to the other formulas.

(89) Q. Can you give me some information as to the method employed by the Postal Telegraph-Cable Company in bonding its employes to insure fidelity to their trust, etc. I understand that the company has some special form of policy. Will you kindly enlighten me. M. T. B.

A. The company handles this matter in the ordinary way and proceeds just as an individual would. Periodically, it makes up a schedule, giving the names of those employes whom it wishes to bond, together with other data, and presents the schedule to an assurance company which issues one policy covering all of the individuals named. Any interim additions or changes are adjusted in the usual way as they occur, this being simply a matter of bookkeeping. The only difference between this class of business and that of an individual is that it is more in the nature of wholesaling.

Self-Winding Clocks in Winnemucca.

The announcement in our issue for January 16, under the head of "Winnemucca, Nev., Western Union," that Mr. S. J. Mercer, manager of that office, had secured forty-one self-winding clock subscribers during the past year, making the average one clock to every forty-five inhabitants, has evoked some favorable comment and admiration for the man who has accomplished so much in so small a place.

"Any man with such hustling qualities," said one gentleman, "should not be permitted to remain in Winnemucca; the company should give him a position where he would have a wider field of activity. It is constantly on the lookout for such men and I, for one, hope that Mr. Mercer's achievement will not pass unnoticed and unrewarded by his superior officials. A man who can get forty-one subscribers in one year for clocks in a town the size of Winnemucca can certainly make good in the commercial department in any large city."

Steel-Destroying Insects. — Italian engineers have, it is reported from Rome, discovered an insect that bores into and destroys steel rails. The worm lives on iron rust. It is presumed that the worm will make no distinction between iron or steel telegraph and telephone poles and rails, as long as there is oxide of iron to devour.

Telegraph Conditions in South Australia.

Government ownership and operation of telegraphs is not what many operators think it to be, and the experiences of telegraphers in countries where the government controls the service are not very encouraging to American operators. The English operators are dissatisfied, and not for the first time; the French operators struck about two years ago to better their condition, and those in Australia have been agitating for better conditions for the past ten years.

The telegraph service in all countries is secondary to the postoffice, and probably never will be placed on the same footing with the postal service. Those in the United States who are clamoring for government ownership should think the second time before giving utterance to their high expectations. It is not necessary to make any investigation on their own account; all they need do is to study the experiences of other countries and ask themselves if, after all, government ownership is what it seems to be.

The following account of telegraph conditions in Australia will be read with much interest at the present time:

There is a feeling of considerable dissatisfaction among telegraphers in South Australia as a result of the attitude of the Public Service Commissioner toward telegraphers in that Commonwealth.

In 1901 the Commonwealth took over the post and telegraph services of the six States which now compose the Australian Commonwealth. These services had previously been governed by independent laws and regulations in the separate States. The Commonwealth constitution provided that officers transferred from State to Commonwealth should "preserve all their existing and accruing rights." The Federal Parliament in passing the Public Service Act reenacted that provision.

The Act appointed a commissioner and six inspectors (one in each State) to classify the service. The commissioner controls salaries and appointments, but is not responsible for carrying out the functions of the department. In his first classification in 1904 he took the strictest legal view of what constitutes a "right," and, finding himself clothed, by delegation, with the powers of Parliament itself in all service matters, he decided to terminate all rights (except the right a small section of the service had to pensions). The compact between the convention which drafted the Commonwealth constitution and the service was thus abrogated by one man, though the Federal Parliament itself had endorsed the compact.

The Commissioner's grading of the telegraphers also created very great dissatisfaction.

The position became acute in 1907, when a Royal Commission was demanded by the service and by the public. That Commission commenced its work early in 1908 and presented its report in October, 1910.

In December, 1910, the endurance of the South Australian officers reached its limit, and negotiations with the Commissioner were broken off, and the Government was appealed to. The deputations which waited upon the Postmaster-General put a clear and strong case.

While the representations to the Government have not resulted in redress of the special South Australian grievances, they secured the abolition of the proportional grading of telegraphers and raised the fifth class maximum to $1,000 for telegraphers, postmasters, clerks and clerical assistants throughout the service, about 4,000 officers being benefited. The fight put up by the South Australian Association also galvanized into vigorous life the branch associations of the "general divisions" and concessions were granted which the government say made a grand total of $1,010,000 for this year. The concessions are very substantial, particularly to the lower grades.

The Royal Commission's recommendations have been largely adopted, but its suggested reform in the system of service control has been turned down by the government. The Commission recommended a board of three directors, one of whom should be a business man of the highest qualifications, the other two to be experts in telegraph and telephonic matters, and in postal affairs respectively, this board to have the responsibility of administration as well as the power to control the staff. Safeguards were suggested whereby the interests of the officers appeared to be protected against mere autocratic action by the Board. The proposal besides involving the abolition of the present commissioner and his inspectors, gave promise of better results both from the public and from the service points of view. The government, however, has decided to continue the present system in spite of the trouble it has given rise to. To meet the demands of the staff for better conditions, it has passed an act placing the service under the jurisdiction of the Conciliation and Arbitration Court.

The position now is that if any dispute arises between the service and the Commissioner, and that official is adamant, the only remedy is to hale him before the Arbitration Court. The Act forbids any costs being granted by the Court. It also provides that any award which conflicts with Commonwealth law or regulations may be set aside by the Parliament. The Parliament therefore is the court of appeal for the Commissioner, but the Act allows no appeal for the officers. An unsympathetic government may easily provide regulations at any time that will anticipate any award likely to be given by the Arbitration Court. From the Commissioner's side it appears to be a case of tossing with a double-headed coin—the officers have so much to contend against that it is doubtful if they will ever take a case to the Court.

The persistency with which the Commissioner decries the work of the telegraphers is one of the chief difficulties the latter have to contend with.

Telegraph and Telephone Age

Entered as second-class matter, December 27, 1909, at the Post-Office at New York, N. Y., under the act of March 3, 1879.

Published on the 1st and 16th of every month.

TERMS OF SUBSCRIPTION.

One Copy, One Year, in the United States, Mexico, Cuba, Porto Rico and the Philippine Islands . $2.00
Canada 2.50
Other Foreign Countries 3.00

ADDRESS ALL COMMUNICATIONS TO
J. B. TALTAVALL, - - - Publisher
253 BROADWAY, NEW YORK.
T. R. TALTAVALL, Editor.
R. J. WEEKS, Manager Advertising Department.

CABLE ADDRESS: "Telegage," New York.
Telephone: 6657 Barclay

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

February 16, 1912.

The International Wireless Treaty.

The United States, alone of the great nations of the world, has so far failed to become a party to the treaty of the International Radio-Telegraph Conference held in Berlin in 1906. The responsibility for this lies with the Senate for failing to give its assent, the matter having been brought before that body at the time the treaty was adopted by the Conference. It is hardly conceivable that such an important matter as this is should have been so neglected.

The situation as far as the United States is concerned is an extremely unfortunate one. This country has no standing in the conference and has no voice in its affairs, although its delegates were largely instrumental in framing the treaty at the Berlin Convention of 1906. Whatever recognition is accorded to this Government is due to international courtesy and not to right. The treaty is based on the principle of mutual help and protection, and it is a serious matter for the United States to be out of harmony with so important a movement.

The United States, instead of being a stranger in the family of nations, wirelessly speaking, should be a leading member of the family, and a ship flying the American flag cannot by right demand or expect to receive aid in time of need. It has no standing and what help it may receive is through the courtesy or charity of its neighbors, so to speak.

There is good reason to believe, however, that the treaty which has lain in the Senate pigeon-hole for so many years will be taken up for consideration and receive confirmation. It is important that this should be done without unnecessary delay in order that the United States may participate in the radio-telegraph conference to be held in London on June 4, on an equal footing with the other nations who have adhered to the treaty. The powers of this conference will be plenary and the United States should by all means possible be in a position to participate in its deliberations.

Corporation Taxation.

The definition of a bright school boy that a politician is one legalized to make trouble seems to have some basis of truth when we contemplate some of the results of these gentlemen's activities. A politician has also been defined as one who follows up business corporations and makes it as unpleasant and expensive as possible for them to exist, and this, too, seems to be tinged with truth. This idea seems to be contagious, for we find these pernicious activities in most all States of the Union and the railroad, telegraph and telephone companies suffer in consequence and are compelled to be on the defensive to protect their rights. Each State has its own way of oppressing business enterprise and the result is that in an interstate commerce business the situation is decidedly unpleasant for the operating companies. Cities and smaller political divisions also add to the general turmoil by joining in the campaign of unreasonable taxation of business enterprise and their zeal sometimes borders on the ludicrous. It would seem that a federal franchise law, under which all interstate commerce corporations should be organized, might simplify the situation, but the States would object to such a law because it would deprive them of large revenues from taxation, etc.

The outlook is not all dark, however. There is an evident reaction in public sentiment toward corporations and we may hope to see the day before long when the State legislatures will deal fairly with public service enterprise.

Universality of the Telephone.

The wonderful development of the telephone and its manifold uses challenges the admiration of every thoughtful person, and it must be a dull mind that does not dwell upon the vast possibilities yet undiscovered. The telephone is revolutionizing social relations and business methods and the time will come no doubt when it will be considered as much a necessity in the family as it is now in business—indeed this time may be considered to have already arrived.

It is difficult for the mind to grasp the idea of the immensity of the telephone industry, especially of the commercial and plant departments, and it is probable that the public does not realize and appreciate what the telephone has done and is doing for the public welfare. It is possible to conduct business and social affairs by telephone and even our spiritual needs are ministered to by its use. Those who are confined to their homes for any reason can listen to church services over the telephone, and many other special uses of the instrument could be cited. One of the latest applications of the telephone is in providing boxes at convenient points along the street, and by carrying a pocket receiver, it is an easy matter to

Digitized by Google

secure a telephone connection wherever one may happen to be.

The possibilities in the use of the telephone seem to be unlimited and each time a new idea is brought forward the question that naturally comes to mind is, "What next?"

How to Study Our Telegraph Lessons.

A student in the Course of Technical Telegraphy now running in this journal makes a statement that is well worth special emphasis for the benefit of all other students. He states that when he read the lessons in arithmetic and algebra for the first time he felt much discouraged to think that he knew so little of what he ought to know, and ascribed his feelings to his own dulness. He laid the papers aside for the time being and later re-read the lessons. The second reading brought additional understanding, and the third, fourth and fifth readings shed such a flood of light upon the lessons that every point involved therein came out clear to him. From this experience he concludes that the lessons should be read and re-read many times in order to get the real benefit of them.

We are very glad indeed that this student has so honestly declared his experiences and feelings in this matter, as it brings to light a highly important fact in connection with study in general —in other words he has simply discovered for himself the underlying truth in regard to study.

It is taught in schools and iterated and reiterated in books that, in order to read understandinglv, it is necessary to read over and over again the subject under consideration. Each reading brings to light points that eluded our attention before, and finally when we have gone over the subject a sufficient number of times we experience a feeling of satisfaction in the knowledge that we have appropriated to our own use about all of the truth the lesson contains.

Many persons are willing to learn but they are not willing to exert themselves to learn. They want knowledge handed to them all ready for use and done up in packages tied up in blue ribbon, but that is one thing that man has never yet succeeded in doing and never will. Knowledge cannot be bought, it must be acquired by systematic and conscientious study. There is only one way to learn and that is to observe and study.

One reading of any article gives us a view of the surface of the subject, that is all. We must dig down underneath the surface to get at the facts, and the deeper we go down the more gems we bring to the top.

Our student's experience is not, by any means, an exceptional case, it is an extremely common one, unfortunately, but he has discovered for himself where the difficulties lay and now he knows his work hereafter will be much easier. This man will unquestionably succeed in his studies, and his experience should form a valuable lesson to others.

Relations of Capital and Labor.

In a recent interview Mr. Theo. N. Vail, president of the American Telephone & Telegraph Company and the Western Union Telegraph Company stated that in his opinion the greatest question before the country today is the question of the relations between the different classes of people.

"The problem is to allay this class prejudice," he said, "and I think it is a simple matter, after all, if taken hold of in a sensible way.

"When one complains about a man having $10,000,000 or $15,000,000, let him stop and ask where is it? It is of course invested in enterprises employing thousands of people; it is not idle cash in a bank which a man can check out at will. This one thought carefully considered ought to answer many complaints.

"Evolution will settle all difficulties between capital and labor and all class questions in this country, I think, without any great trouble. All sorts of experiments will be made, but we shall come out all right in the end."

Highest Wireless Tower for San Francisco Exposition.

A memorial tower, 1,350 feet above sea level, is to be erected in Lincoln Park, San Francisco, Cal., as one of the features of the Panama-Pacific International Exposition in 1915, and its possibilities as a wireless station has led Secretary of the Navy George von L. Meyer to refer to the subject as follows:

"The Navy Department is taking steps towards erecting a high-power station on the California coast, in connection with its chain of wireless stations across the Pacific and for communication with ships in the eastern Pacific Ocean. Since the range of wireless depends principally upon the height of the aerial wires above the ground, and since the location of this station at San Francisco would be most advantageous to that city, it would seem that the Memorial Tower should be erected with a view to its use for supporting one end of an aerial of the most powerful wireless station in the world. The Eiffel Tower in Paris, 1,000 feet high, has produced wonderful results in long distance wireless work, and the proposed tower, 1,350 feet above sea level, would insure even more remarkable results.

"A site near the ocean beach at San Francisco will give ideal wireless conditions, there being no tall buildings or trees in the sending direction, and I strongly recommend that, before the exact site of the Memorial Tower is selected, the Navy Department be consulted as to the needs of the proposed wireless station. Such a station would in no way interfere with the use of the tower as an observation station for visitors, or for its use as a weather station. The small wires of the aerial could not detract in the slightest from the appearance of the tower, while adding greatly not only to its utility, but to its attractiveness for visitors."

Course of Instruction in the Elements of Technical Telegraphy—IX.

(*Copyrighted.*)

(Continued from page 80, February 1.)

[We began in our issue for October 16 the publication of a course of instruction in technical telegraphy. The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and is divided into chapters, following one another in logical order.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases, and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.]

Electricity.

POTENTIAL, CURRENT, RESISTANCE.

(*Continued.*)

In any combination of metals used to develop a difference of potential the metal which has the greater affinity for, or tendency to combine with, the electrolyte becomes the positive element. With any two in the following list of metals the first will be the positive, and the other the negative element. For example, using zinc and copper, the former being the first on the list becomes the positive or generating element, and the copper the conducting or negative element. If copper and silver were used, however, the copper would have the greater affinity for the electrolyte and would become the negative pole of the cell.

TABLE I.

1. Zinc	7. Bismuth
2. Cadmium	8. Antimony
3. Tin	9. Copper
4. Lead	10. Silver
5. Iron	11. Gold
6. Nickel	12. Platinum

13. Graphite

In a simple voltaic cell the effect of the momentary current resulting from a metallic connection of the poles is a decomposition of the electrolyte. The water of the solution is decomposed, its oxyated and appears on the surface of the copper in the form of bubbles of gas. As a result the copper plate becomes in a short time coated with hydrogen bubbles which have the effect of raising the potential of the copper to nearly the same electrical level as that of zinc and thereby seriously diminishing the current strength. This formation of hydrogen on the copper plate is known as polarization, and its removal by any means, mechanical or chemical, is called depolarization.

In the form of cell generally used for telegraph purposes depolarization is secured by surrounding the copper plate with a solution of copper sulphate, with which the free hydrogen may combine. This combination usually merely disposes of the hydrogen and prevents the detrimental effects of an accumulation of this gas on the copper plate.

So far we have seen that a difference of potential constantly maintained will generate a continuous current, but the strength of the current is affected by another important factor, namely, Resistance.

Resistance is the opposition, or resistance offered by all bodies to a flow of electricity.

A body which offers a small resistance to the current flow is termed a Conductor. A body offering a very high resistance to the current is termed an Insulator.

Table II gives a few substances arranged in the order of their value as Conductors and Insulators.

TABLE II.

Conductors.	*Insulators.*
Silver	Dry Air
Copper	Ebonite
Other Metals	Shellac
Charcoal	Gutta Percha
Saline Solutions	Silk Glass
Ordinary Water	Porcelain
	Dry Wood

Units, or fixed standards for measurement, are required in electrical work, so that all observations, wherever made, may be comparable. Thus, using the pound as a unit of pressure, the pressure of an engine can be expressed as so many pounds; using the mile as a unit, a distance can be expressed as so many miles; or, in the case of a fluid using the gallon as a unit, a quantity as so many gallons.

To express electrical pressure, or difference of potential, the volt is used as the unit; to express resistance, the ohm; to express current, the ampere.

The volt is that pressure, which, in a circuit of one ohm resistance, will generate a current strength of one ampere.

It may assist the student to a more thorough comprehension of the terms electromotive force, resistance and current, if we illustrate these three by some familiar figure, such as a cyclist.

Suppose, in a given run, the cyclist's speed to be uniform and to be entirely due to his strength, and the condition and length of the road, then electromotive force might be represented by the rider's strength at starting, resistance, by the length and quality of road, and current by his uniform speed.

In using speed as a comparison to current, it must not be considered in any relation to time, but simply as a quantity, the magnitude of which depends on the cyclist's strength, and the road conditions.

The exact relationship which electromotive force, or difference of potential, bears to resistance and current will be given in the chapter on Ohm's law.

Telephone Pioneers of America.

ANGUS S. HIBBARD.

Mr. Angus S. Hibbard, the subject of this sketch, was one of the leading spirits in bringing about the organization of the Telephone Pioneers of America. He was born in Milwaukee, Wis., on February 7, 1860, and received his education in that city and at Racine College. He entered the telephone service in Milwaukee, on July 1, 1881, and has been prominently identified with the business ever since. He has filled successively the positions of superintendent of the Wisconsin Telephone Company, general superintendent of the American Telephone & Telegraph Company, vice-president and general manager of the

ANGUS S. HIBBARD,
New York (1881).

Chicago Telephone Company and now holds a position in advisory relation, executive department, American Telephone & Telegraph Company, with headquarters in New York.

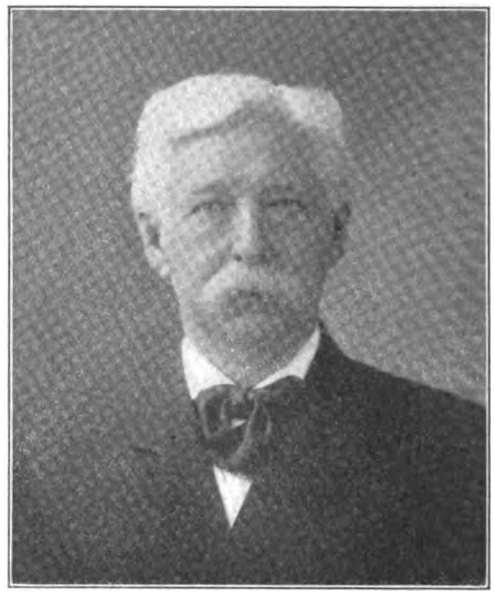
Mr. Hibbard is thoroughly familiar with the work of all the departments of the company's business, and is the inventor of a number of telephonic appliances and methods now in general use. He is a lover of music, and has much talent in this direction being the composer of a number of excellent operettas and songs. He is much interested in out-of-door sports and is an enthusiastic golfer.

T. B. DOOLITTLE.

Thomas Benjamin Doolittle, Sc. D., of Pine Orchard, Branford, Conn., is one of the earliest of the telephone pioneers, and performed valuable work in the development of the telephone industry.

Apart from his experimental work on apparatus, which resulted in many fundamental appliances still indispensable, Mr. Doolittle was engaged on the broad lines of development of the telephone business into a national and international system, making a local study of every city and state, also of Canada, as to its business relations or trend of business to towns, cities and states, in order that lines should be built not only to meet the requirements, but by the most economical arrangement. He maintained that the fundamental principle of the telephone was unique and unlike that of any other public service in the world, and that for the best interest of the public, every telephone subscriber must be able to connect with every other subscriber in one comprehensive system covering the entire country. Many investors have ignored this principle to their great sorrow.

For many years up to his retirement from active service (June, 1909) he had a corps of able assistants in this work of commercial and traffic engi-



THOMAS B. DOOLITTLE,
Branford, Conn. (1877).

neering. These assistants accompanied him from place to place, were very enthusiastic and worked almost incessantly in season and out of season, as they appreciated the scope and value of the work.

Mr. Doolittle was the father of the hard-drawn copper idea, and he brought the manufacture of this wire to a high degree of perfection. For this work he was awarded the Edward Longstreth Medal by the Franklin Institute of Philadelphia.

Mr. Doolittle entered the telephone service in June, 1877, and his telephone experience is almost as old as the telephone itself. The degree of Doctor of Science was conferred upon him by Dartmouth College on June 30, 1909, his seventieth birthday.

New Year's Greetings from San Salvador.—We are in receipt of New Year's greetings from the officials of the general administration of telegraphs and telephones at San Salvador. The Salvadorean telegraph and telephone department is a progressive branch of the government and the officials are bringing it up to the highest standard of efficiency.

Why Aluminum Is Not Good for Telephone Wire.

A bulletin of the National Electric Light Association, New York, contains an interesting discussion of the conductivity, tensile strength and other properties of aluminum wire.

Some of the physical constants of aluminum as it is now manufactured commercially for electrical purposes, says the *Electrical World*, are as follows: Melting point, 1,157 degrees F.; elastic limit, 14,000 lbs. per square inch; ultimate strength, 26,000 lbs. per square inch; modulus of elasticity, 9,000,000; electrical conductivity, 62 per cent; specific gravity, 2.68; coefficient of linear expansion, .000,012.8. At present aluminum is used only to a limited extent for large conductors. Its use is thus restricted because of the practical impossibility of employing the ordinary methods of soldering, due probably to the fact that its surface seems to have a coating of oxide on it at all times.

The bulletin of the association discusses the question of cost as follows:

"At the present relative cost of the two metals, aluminum is about 10 per cent to 15 per cent cheaper than copper of the same resistance. The weight of a unit length of aluminum wire is only 47 per cent of a copper wire of the same length and resistance. Consequently, aluminum can cost 2.13 times as much as copper per pound and still cost the same as copper per unit length from the standpoint of electrical resistance. As a matter of fact, however, the price of aluminum at present is less than 2.13 times that of copper per pound, so that it is actually cheaper to use aluminum as an electrical conductor than copper, where other considerations do not enter."

Investigations made into the subject by other authorities, however, seem to indicate that there is another factor entering here which would throw the conclusion in the opposite direction. This is the fact that the aluminum market is so centralized under one common control that there is no market for aluminum junk, and this monopoly feature makes it impossible for operating companies to figure that aluminum has any junk value.

The bulletin goes on to say that expansion and contraction with changes in temperature is greater than in copper. A solid wire of small size gives a great deal of trouble through breakage due to crystallization of the wire from swaying in the winter. The greater expansion and contraction make it necessary to be especially careful to avoid stringing lines too tight in warm weather. The increased sag necessary for aluminum makes the liability to crosses unduly high.

Joints between copper and aluminum wire give a great deal of trouble due to electrolytic action.

A Famous Singer and Old-Time Telegrapher in Want.

A Chicago dispatch of January 24, published in the New York newspapers, states that Mr. Jules Lumbard, a forty-niner of the telegraph and a celebrated singer of patriotic songs during the civil war, is living in that city in dire poverty. He was a brilliant man in his day and was associated with John A. Creighton, of Omaha, who built the first telegraph lines in the West during the days when the Indians were numerous and warlike.

Fifty years ago Mr. Lumbard and his brother Frank, toured the country singing "The Battle Cry of Freedom." They made famous all of George P. Root's songs and made "The Battle Cry of Freedom," so great an instrument for the inspiration of patriotism that Abraham Lincoln once said at a public banquet:

"Let me tell you that two men—and they are not military men—by their singing have got more men to enlist in the United States Army than fifty times one hundred and fifty of our best recruiting officers ever addressed."

In the sixties Mr. Lumbard sang in Henry Ward Beecher's church in Brooklyn, N. Y., and in 1905 he attended the old timers' reunion at New York on which occasion he delighted the members with some of his famous songs.

Like most men of his kind, however, he never appreciated the value of money and his purse was always open for the aid of others. Although he is now eighty years of age he is a man of commanding presence and well preserved.

New Book.

TELEPHONY. By Samuel G. McMeen and Kempster B. Miller. 948 pages, 671 illustrations. Chicago: American School of Correspondence. Price $4.00.

This latest addition to the literature on the telephone has a decided advantage in being the product of two men whose knowledge of and experience and reputation in telephony are unquestioned. They are both among the most active and leading telephone men of the time, and what they say regarding the art may be accepted as authoritative and up to date.

The book is designed with the care that comes from knowledge and experience, and is a complete exposition of the art of telephony, both in theory and practice. Every drawing used was especially prepared for this work, and each one has the valuable merit of being clear and distinct.

The work has fifty-three chapters, Chapter forty being devoted to telephone train dispatching. A partial list of other subjects treated of in the various chapters includes: History and development, acoustics, lines, transmitters, receivers, primary cells, electromagnets and inductive coils, condensers, selective and non-selective party-line systems, protective means, switchboards, private branch exchanges, intercommunicating systems, traffic; phantom, simplex and composite circuits, lines, cables, poles, etc., underground construction, wiring, testing, etc. From this list an idea may be gained of the scope of the work, and railroad men will be especially interested in the book by reason of the special chapter on telephone train dispatching, which describes in a general way the various systems in use.

Copies can be procured of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York, on receipt of price.

Efficiency of Accumulators*.

BY W. HIBBERT.

If the efficiency of an accumulator is compared with an engine or dynamo, it seems to be low. The difference is not so pronounced if the operations of charge and discharge are of small duration and follow each other at once. But where a discharge runs on for seven or eight hours and is then followed by a corresponding charge, the efficiency found is somewhere near 80 per cent. Now, the work done in charge or discharge depends on three factors—volts, amperes and hours—and under favorable conditions a good battery will return almost as many ampere-hours as were put into it. The loss in the quantity of electricity will not be more than 3 or 4 per cent.

This is only another way of saying that the chief factor in determining efficiency is the difference of voltage during charge and discharge. During charge, the average volts are nearly 2.2, while during discharge the average figure is about 1.95 volts. This factor alone, therefore, would determine an efficiency of about 88 per cent. It is evident that any appreciable improvement in efficiency must arise from a closer approximation between the charge and discharge voltage. The latter must be raised or the former diminished. Resistance accounts for less than half of the 12 per cent. loss in volts. It may be responsible for about 5 per cent. of the total. That it does not cover the whole loss is shown by the fact already mentioned, that short cycles (a few seconds charge or discharge) show improved efficiency.

To account for the unallotted remainder, we must go to the fact that the electromotive force is also different in the charge and discharge, and the question arises whether there is any chance of diminishing this difference. Since the researches of Dr. Gladstone and the present writer it has generally been admitted that changes in E.M.F. depend on differences in acid strength in the pores of the plates, and known effects of electrolysis enable us to see how such differences arise.

During discharge the acid is abstracted from the liquid in the pores, which is therefore necessarily weaker. During charge, the electrolytic wandering of the ions makes the acid stronger in the pores of the positive plate, where it is most efficacious in raising the voltage.

In thinking of these things it occurred to the writer that this source of loss might be lessened by the following device. The efficiency of two similar cells was determined by charging the plates in weak acid and discharging them in stronger. In other words, at the end of a charge the plates were lifted from a box containing weak acid and put into another containing strong acid. made. The current was kept at a predetermined value, and the potential difference read on a sensitive voltmeter.

At the end of a cycle the readings of the voltmeter were plotted against ampere-hours in the usual way, and the work put in during charge and that given out during discharge obtained from the enclosed areas.

It was thought that it would be too laborious to go through the usual repetition of cycles until constant results were obtained, and the early results were therefore compared with two similar cells in which the acid remained unchanged. In the final result, however, the experiments were repeated often enough to show that constant figures were being obtained.

All the cells were charged and discharged in series, so that the ampere-hours were the same for all. The voltage limits laid down were 2.4 for charging and 1.8 for discharging, as shown by the ordinary cells.

By the change in acid, a lower voltage sufficed to charge, this advantage being somewhere about 0.06 volt. Similarly, a higher voltage was obtained in discharge, though the advantage here was only about 0.02 volt. The net result was of such an order that the efficiency was raised by about 5 per cent., say, from a value of 85 to one of 90 per cent. This is not quite so large as theory would suggest, but the reason is soon found. The method adopted is able to change the strength of the acid in the body of the cell at the appropriate times, but it is the liquid in the pores of the active material which determines the E.M.F., and this is changed merely by the slow process of diffusion. Hence the mechanical changing of the acid only partly accomplishes what was proposed, and so far fails to give the full effect desired.

We are brought once more to see what was asserted in Gladstone and Hibbert's paper, that an increase in the rate of diffusion would help. If diffusion could be so expedited that the acid in the pores could never differ much from that outside the plates, the charging voltage would not exceed the discharging value by more than $2\,I\,R$. As a matter of fact, there is no chance of making diffusion take place rapidly enough, but as its rate increases with rising temperature, some efficiency cycles were taken at 30° or 40° C.

Two cells were placed in a water bath kept at about 37°, and placed in series with two similar cells standing in the ordinary air at an average temperature of 19°. Many cycles were taken, and gave practically the same result. (In these experiments the acid had the same strength in all four cells: temperature was the only difference.) The following table shows the general nature of the results:

Effect of temperature on the efficiency of an accumulator. Discharge current, 1.5 amperes; charge, 1.3 amperes:

	Ordinary Temperature	37° C.
Discharge watt-hours.....	14.0	14.84
Charge watt-hours.....	17.16	16.67
Efficiency	81.5	89.0

The average voltage of the warm cells exceeded that of the cold cells by about 0.07 volt. During discharge the difference was small.

*London "Electrical Review."

Digitized by Google

The net result of these experiments shows that the efficiency of accumulators can be increased by two distinct methods. Both of these methods depend on the same theory, and, so far, they afford additional verification of the theory.

Whether either of the methods is capable of being used in practice is a moot question. Changing the acid twice in every cycle is an impracticable process. Keeping the temperature up is comparatively easy, but before it could be seriously proposed, the effect on "life" would have to be considered. Such evidence as is already to hand indicates that local action increases rapidly with temperature, and, therefore, that disintegration of the positive plates would probably be accelerated. Such a result would more than counterbalance any good accruing from increased efficiency. For the moment we must be content to look on the foregoing results as interesting demonstrations of the losses arising in accumulators. We are confronted by the facts that an increased rate of diffusion increases capacity and efficiency, but if it depend on higher temperature it will probably shorten the life of the cells.

An Extensible Mast for Wireless Telegraphy.

An extensible metallic mast which possesses some novel features is being tried in Germany. The apparatus is called the Fontana mast, and it was designed to provide a metallic mast which can be quickly raised or lowered, but without the disadvantages of a telescopic mast.

The Fontana mast is of interest owing to the new principle involved, and it is claimed that the design overcomes most of the drawbacks which up to the present time have limited the appplications of such masts in electrical work. A four-sided hollow mast is formed of four flexible steel strips. The edges of these strips have teeth cut in them in such a way that the teeth of one strip interlock with the recesses of the adjoining one, so as to join the four strips at their edges. The teeth project to some extent. This makes up a hollow column. In order to brace it thin sheet-steel brace plates are placed at frequent intervals.

The mechanism for raising or expanding a mast of this kind is simple. The steel strips are wound upon drums and a second set of drums is mounted below to feed out the strip and guide it properly. These latter drums have projecting teeth around the center which engage in holes in the steel band. A chain drive connects both drums, and the lower or feeding rollers are driven by a hand crank or in other cases by an electric motor.

As the four steel bands pass up through the guide plate they become interlocked and form the steel tube. Upon the guide plate is a pile of section disks. The top head of the mast carries the first of a set of links which go to join all the section plates. When the head rises in the first place, it picks up the first section disk by means of the first four links placed on the four sides, so that the disk is automatically fitted around the column. As the mast continues to rise, the second disk is taken along in the same way; the result is that the section disks are situated all along the mast, their spacing depending on the length of the link which is determined according to circumstances. A light portable mast, such as is used for wireless telegraphy, can be raised to sixty-five feet in height using a base about three and a quarter feet square. When lowered, the height of the apparatus is only six feet and it weighs 385 pounds. The bending stresses are taken up by a short column, which projects up the center and transmits the stresses to the base. Means are provided for clamping the base of the mast tightly against the bottom column.

A crank attached directly to one of the drums, or by gearing, can be used for raising and lowering the mast and the remainder of the drums do not need gear drive, as the rest of the strips are drawn along by means of the interlocking teeth.

The Fontana masts are made in sizes to reach a height of eighty feet and carry a load of two tons. The manufacturer is the Fontana Maste und Träger Gesellschaft, Berlin, Germany.

Telegraphers of Today.

An excellent opportunity is offered to telegraph people in general to become acquainted with over 600 prominent telegraph officials and others identified with the telegraph, the railroad, the submarine cable and press associations of the past generation, through their portraits and sketches of their careers as published in "Telegraphers of Today."

This work was issued in 1894 and includes biographical sketches of all the individuals connected with the interests mentioned at that period, many of whom have passed away from their earthly labors. The younger generation, however, will find much of interest in looking upon their portraits and reading of their achievements in life. Many of them are still alive and in harness in the telegraph and other fields of activity.

Mr. J. J. Ghegan, president of J. H. Bunnell & Co., New York, who recently received a copy expresses his appreciation of the work as follows: "Copy of 'Telegraphers of Today' received. I casually saw a copy of the book when first published, but never had I an idea that it was so beautiful, interesting and historically accurate. It should be of great interest to telegraphers with any sentiment in their makeup. It is magnificent, unique and I truly pity those of the fraternity who fail to secure a copy before the edition is exhausted."

This book, which is 11½ x 14 inches in size, was originally published at $5 per copy, but in order to close out the remaining copies we offer them at $1 per copy by express, charges collect.

The Telegraph in Ye Olden Days.

BY T. J. CUSACK, NEW YORK.

At a recent book sale I purchased a copy of an old history of the telegraph, published in 1852, giving information and statistics that are interesting and somewhat amusing to the telegraph man of today. A few extracts might be worth reprinting, to show by comparison the wonderful strides made in this important branch of industry within the memory of many, in fact within a space of years encompassed by the telegraphic careers of some who are now engaged in the business.

In a chapter showing the cost of building and operating the telegraph lines in the year 1851, the historian states: "The aggregate cost of materials consumed in working all the telegraph lines on the continent for one year may be summed up about as follows: Metallic zinc, say $3,000; nitric acid, $2,000; mercury or quicksilver, $600; breakage, wastage, etc., $500; total, $6,100. By this statement it will be seen at what comparatively small expense of materials the electric fluid is daily sped to all parts of this vast country. Further improvements will likely reduce the present cost of materials."

The cost of construction of lines is estimated at from $150 to $200 per mile. There were four principal companies in the field at that time, Morse's, Bain's, House's and O'Reilly's, with many lesser companies, connecting lines, throughout the country, comprising a total mileage estimated at from 12,000 to 15,000 miles and extending east to Halifax, west to St. Louis, and south to New Orleans by two routes, one via Richmond, Savannah, Montgomery and Mobile, the other by way of Pittsburg, Cincinnati, Louisville and Nashville.

A prediction is that: "As soon as the Indians are brought into peaceable subjection and a good highway is established from Missouri to California, electric telegraph lines will be built over the entire route.

"The offices in New York," the story continues, "employ on an average of four young men in each, as operators and clerks. Those acting as clerks are generally also capable of writing with the instruments. In country offices, or in places of small note, one or two operators are sufficient. The wages paid for their services differ in different places. The chief operator receives the highest wages—varying from $1,000 to $1,200 per annum.

"Some companies also employ a person known as the superintendent of their lines, who has the immediate control and supervision of the whole. It is customary with the most, if not all the offices, when the operators have reached the hour for closing, or have finished their day's work, if required by the press or other parties, to keep open for a longer period to charge those giving the order, extra for their services. As two have to sit up in each office, the usual charge is 50 cents per hour, for each person, or $1 per hour for each office.

"The offices in New York manage the delivery of their own messages. For this purpose they employ on an average about five boys each, for twelve offices, making an aggregate of about sixty boys. The wages paid these boys is from two to three cents for each dispatch delivered, if below Canal street, or within about a mile from the offices. If beyond that distance or after night, the charge is 12½ cents for each dispatch. If in distant parts of Brooklyn or Williamsburg, the charge is 25 cts.

"Besides the help previously referred to many offices employ what may be termed a batteryman whose duty it is every night to remove the zinc cups from the acid cells or cups, and, after cleansing them in clear water, to set them by until they are required for use the next day.

"The telegraph is used to a great extent in conveying secrets of rise and fall of markets; for instance, a man may be purchasing goods in New York, gives his reference to the merchant and by the aid of the telegraph he can know the standing of his customer, even before the purchase is completed.

"There are bankers, brokers, etc., in Wall street, that receive and send, on an average, six to ten messages per day, throughout the year."

The *Herald* of May 9, 1851, is quoted "to illustrate the speed with which news is sometimes transmitted" as follows: "The 'Europa' reached her wharf yesterday at half past six a. m. Her news was at the O'Reilly telegraph office, 181 Broadway, somewhere before 7, previous to the office being opened. The Pittsburg office got to work about 8 a. m. and the dispatch commenced going to New Orleans ten minutes past eight, and was received and put up in the Exchange before 9 a. m. and the acknowledgment of its receipt, as at foot, reached the O'Reilly telegraph office, New York, at quarter past eleven, thus having travelled from New York to New Orleans and back in three hours and five minutes.

"O'Reilly's Telegraph Office,
"New Orleans, May 8.

"To Smith, Chief Operator,
"New York Office:

"The foreign news per 'Europa,' signed 'Jones,' was received here before 9 o'clock a. m., New Orleans time.

"(Signed) Zook, Chief Operator."

This news, in its transmission, as will appear from the following note from Mr. Baily, clerk in the O'Reilly telegraph office, was only rewritten three times:

"181 Broadway, May 8.

"I have to state that the foreign news by the 'Europa' was forwarded from this office at 8h. 10m. a. m. It was only rewritten at Pittsburg, Louisville and Tuscumbia before reaching New Orleans, where it was received and hung up in

Digitized by Google

the Merchants Exchange before 9 a. m., New Orleans time. The message acknowledging its receipt as above was received at this office at 11:15 a. m.

"(Signed) Baily, Operator."

The *Herald* would whistle a different tune if this sort of service was passed out to it today and a communication would be forthcoming from our old friend Peter Flynn.

Telephone Service in New York City.

The number of telephones in New York City increased about 10 per cent. during 1911, according to Mr. R. S. Scarburgh, special agent of the New York Telephone Company, New York, During the past twelve years the total increase has been 700 per cent., until today there are in service in New York City 440,000 telephones. These telephones are served through sixty-four central offices, and are connected by 1,196,821 miles of wire. An average day's telephone business in New York City means 1,900,000 messages. This is about four messages per day from each telephone.

A new type of public telephone, known as the multi-coin prepayment machine, has been perfected and is now being installed in all of the boroughs. This new type of instrument is superior to the old type of prepayment telephone because it eliminates a great deal of the time that was consumed formerly in getting connection and then calling back to the patron to drop the coin in the proper slot before the connection was completed. The new telephones take nickels, dimes and quarters, and can be used to send any class of telephone messages, local, suburban or long distance, and also to send telegrams.

During the past year a change was made in the method of calling Philadelphia subscribers over the long distance wires, with the result that service between New York and Philadelphia is now on what is known as a "two-number" basis, that is, a person can call for a number in Philadelphia in the same manner as he would ask for a local call. This method serves to cut down the time of making connections between New York and Philadelphia to less than one minute.

Telephone Consolidations in Northern New York.

At the annual meeting on January 19 at Saranac Lake, N. Y., of the stockholders of the Mountain Home Telephone Company, the independent telephone company operating in that vicinity, formal steps were taken to bring about the consolidation of the telephone systems of the independent companies and the New York Telephone Company operating in the entire mountain, lake and St. Lawrence districts of northern New York, with the result that the 240,000 inhabitants of this section will be given a comprehensive service, both local and long distance, and the duplication of telephone systems eliminated.

The new service is to be under the direction of representative business men in each locality in which the new company will operate, and these men will make up the new board of directors to the number of fifteen.

In the new arrangement approximately 12,000 telephones are involved and about 900 miles of toll lines. The property values are in excess of $2,225,000.

The properties involved in this new enterprise are the Mountain Home Company, of Saranac Lake, the Clinton Telephone Company of Plattsburgh, Dannemora, etc., the Adirondack Home Telephone Company of Malone, Norwood, Canton, Potsdam and neighboring towns, and the properties of the New York Telephone Company in the four counties. Ogdensburg and Gouverneur, in which there are no competing telephones, are to be included in the new company's territory.

The toll line users in this area will all have access to the toll lines of the New York Company and the long distance lines of the American Telephone & Telegraph Company, in addition to the comprehensive county and inter-county systems now operated by the independent companies.

It is expected that the unification of service will be well under way by May.

Wireless Examinations.

In answer to many inquiries regarding the qualifications of wireless telegraph operators who wish to enter the government service, *Wireless News* prints a portion of a United States Civil Service bulletin, showing in a general way what the government examination requires applicants to know. The examination covers the following subjects with the percentage rating given to each:

	Subjects.	*Percentage.*
1.	Spelling (20 words of more than average difficulty)	5
2.	Arithmetic (fundamental rules, fractions, percentage, interest, discount, analysis, and statement of simple accounts)	5
3.	Penmanship (the handwriting of the competitor in the subject of report writing will be considered with special reference to the elements of legibility, rapidity, neatness, general appearance, etc.)	5
4.	Report writing (test in writing in letter form a report of from 150 to 200 words in length, summarizing and arranging in logical order a series of facts included in a given statement of 400 or 500 words)	5
5.	Copying and correcting manuscript (test in making a smooth corrected copy of a draft of manuscript which includes erasures, misspelled words, errors in syntax, etc.)	10
6.	Practical questions	20
7.	Practical experience as wireless telegraph operator	50
	Total	100

Wireless Telegraphy on the Atlantic Coast of the United States.*

BY JAMES L. CHARLTON.

On the Atlantic seaboard of the United States there are fifty-four wireless-telegraph stations fully equipped, all of which are operated by the United States army and navy, the United Wireless Telegraph Company, the Marconi Company and the United Fruit Company, divided as follows: Twenty-two by the navy, seven by the army, sixteen by the United Wireless, seven by the Marconi Company and two by the United Fruit Company. In addition to these the navy operates five stations in the West Indies and Central America, the United Wireless three and the United Fruit Company six. The government stations are primarily for departmental service, although under certain conditions some of the naval stations—for instance, Key West, San Juan and Colon—are also open for commercial business. In addition to the above there are a number of stations used for experimental purposes or operated by other companies and by private individuals, but their influence is wholly local. At best they are of little importance except to cause interference with the transaction of government and commercial business. To this statement there is one exception, namely, the station of the *New York Herald* situated at the Battery in New York harbor, which stands ready at all times to give aid to navigation and twice daily sends out weather reports and news items. By constantly improving and weeding out defects, the stations mentioned are today in first-class operation and do an amount of work daily that would no doubt surprise the average person.

The naval stations extend from Cape Elizabeth, Me., to Key West, Fla., with two on the Gulf Coast —one at Pensacola, Fla., and one at New Orleans, La. There is also a high-power station at Guantanamo, Cuba, the winter base of the Atlantic fleet, and there are two stations at the Isthmus of Panama, situated one at Colon and one at Porto Bello. By relaying a message may be sent from one extreme of the navy circuit to the other without the slightest doubt that the message will reach its destination. The speed of transmission and the amount of relaying vary at different times of the year, due to the influence of atmospheric electricity during the summer months in the southern zones. Although this obstacle has been overcome to some extent by increased efficiency of operation and the use of high-frequency sparks, it is still a source of great annoyance.

Besides handling the official business of the navy and keeping war vessels anywhere within 500 miles of the coast almost constantly in touch with the department at Washington, the naval stations send out a noontime signal each weekday, followed by the weather report for the vicinity in which the station is located, and also, when storms are brewing, warnings received from the Weather Bureau. Ships in distress can always call these stations.

The equipment of the navy stations varies and numerous types of apparatus are used, although the receiving is almost entirely done with perikon detectors and transformer, telescopic-type tuning coils, a carborundum or silicon detector being cut in when there are strong static effects or a ship close by is signaling.

The high-power stations at Key West, San Juan, Guantanamo and Colon are equipped with high-frequency sending sets of 35-kw. rating, and were designed to be intercommunicative; in fact, they are so during the night and under favorable conditions during daylight. The navy-yard stations located at Brooklyn, Washington, Charleston and Pensacola are of from 10-kw. to 15-kw. rating, and have an effective range of about 500 miles. Sending sets of 3-kw. to 5-kw. rating were installed in the other naval stations, while most of the fortifications and lightships have 1-kw. sets.

The Navy Department is gradually developing a standard transmitting unit, which will overcome some of the defects in the present equipments and be capable of transmitting with a wide range of wave lengths. A transmitter capable of a wide and quick change in wave lengths is very desirable; for in case of war and with the enemy trying to interrupt wireless communication, the wave lengths could, by a prearranged schedule, be changed until communication is established. In some of the sets being tried out on shipboard this is done with a very loose coupling and by plugging in sections or individual turns on the closed circuit helix. A variation of wave lengths from 300 meters to 1,100 meters and in some cases 2,000 meters has thus been used in cases of strong interference with good success.

The Navy Department has now a standard mast or tower for antenna suspension and will gradually replace the old wooden poles at all of the important shore stations. It is constructed of light angle iron and built in the form of a pyramid, being 9 feet square at the base and tapering to 2½ feet at the top. Surmounting the top is a short wooden mast to which the antenna insulators are attached. The mast from base to extreme top is 200 feet high and rests on a wooden insulated platform. The recent equipment of the Newport station with two of these towers placed 550 feet apart has made that station one of the most important on the coast and has greatly extended its range of operation, with a record of communication with Colon, Panama, a distance of nearly 2,000 miles.

The new naval station now under construction at Arlington, near Washington, will have three towers, one 600 feet and the others 450 feet high. The equipment of this station will be ideal in every respect and when completed it will be one of the most powerful in the world. A twenty-four-hour watch is stationed at all naval shore stations year in and year out, there being, as a rule, four operators with a chief operator in charge.

Since the passage of the wireless-telegraphy act, which took effect July 1, 1911, there has been necessarily a large increase in installations on ships of all descriptions, and a great many of these installations

Electrical World, New York.

Digitized by Google

have been by the United Wireless Company, which, in conjunction with the United Fruit Company, controls nearly all the commercial wireless business to and from steamers operating on the Atlantic coast of the United States, Mexico, Central America and the West Indies. Twenty-one of the United Fruit Company steamers carry wireless stations, and the Atlantic division of the United Wireless Company operates some 240 stations aboard vessels. An effective chain of commercial stations extends from Eastport, Me., to Galveston, Tex., the average distance apart being 200 miles, consequently coastwise shipping is at all times within range of shore communication. It may be added that the Key West naval station handles the messages in that vicinity for both the United and the Marconi Company.

The United Wireless equipment for ships is a standard set of 2-kw. rating with direct-coupled transmitter and tuning coil, the receiving being done with carborundum detectors. The more important commercial shore stations, such as Eastport, Sparrow's Point, Cape Hatteras, Tampa, New Orleans and those in Central America, are of 5-kw. to 10-kw. rating, while the intermediate stations are of 2-kw. rating. Taking into consideration the rating of the sets, this company does excellent work and has a system of relaying that is very satisfactory.

When at sea, ships with United Wireless equipment make daily reports of their 8 a. m. and 8 p. m. position, and handle messages from ship to shore or vice versa. A news bulletin is published once or twice a day, and on ships that are at sea for a day or more at a time these bulletins are inserted in an attractive booklet and sold as a souvenir. The press items for the bulletin are sent out by Atlantic City, Norfolk, Hatteras and Key West stations between 8 and 10 o'clock each morning, and at night by Atlantic City at 8:30, and by the *New York Herald* station at 9:15, which repeats at 12:30 a. m.

While the United Wireless Company monopolizes practically all the north and south commercial wireless business of the Atlantic coast, the Marconi Company similarly monopolizes the transatlantic business. This company has seven stations on the Atlantic coast; four of these are bunched close together between Cape Cod, Mass., and Sea Gate, L. I. Of the others, one is at Cape May, N. J., one at Virginia Beach, Va., and the other at Palm Beach, Fla. These last three stations have only lately been installed. The Marconi Company does a large business in messages and works very effectively. There are about eighty transatlantic ships which have Marconi installations, none being in excess of 2.5 kw. These ships do not individually do much long-distance sending, such communication being by relay, as there is practically always a chain of ships stretching across the Atlantic.

Three stations handle the New York business, namely, those at Siasconset, Mass.; Sagaponack, N. Y., and Sea Gate, N. Y. Cape Cod handles the Boston end, Cape May the Philadelphia end and Virginia Beach and Palm Beach handle the business from any Marconi ships that happen to be bound south. There are also three stations on the southern coast of Nova Scotia which receive or transmit messages to the United States by land wire.

With the exception of Cape Cod, none of these stations is of high power. At Cape Cod (Wellfleet, Mass.) there are two stations, one of high and the other of low power. The low-power station is used for local work during the day and the other, which is of 75 kw. and has a wave length of 1,800 meters, is used for press and long-distance messages at night. The large antenna of the high-power station is used only for transmission and not for receiving messages. This station has a duplicate at Poldhu on the western coast of England, and each station has a maximum radius of transmission of about 1,500 nautical miles. When midway across and when there is no abnormal static effect, the liners often copy the press messages from both sides during the same night.

Marconi operators are furnished with a magnetic detector for medium-distance work, and for long-distance work the Fleming vacuum-tube rectifier is used. This detector was brought out some years ago, but met with little success until lately, when improvements were made, and it is now equally sensitive with the perikon detector, although not nearly so simple. This rectifier consists essentially of an incandescent lamp of about five candle power, the filament of which is brought to incandescence by a battery, usually of storage cells giving from twelve to eighteen volts, there being a certain critical point which is controlled by a variable resistance placed in series with the filament. Surrounding the filament is a platinum plate connected to a leading-in wire fused in the opposite end from the filament. When one lead from the receiving circuit is connected to one terminal of the filament and the other lead to the platinum or cold electrode, the oscillations in the antenna are caused to pass only in one direction through the rectifier, thus producing a direct current, which is made to act upon a telephone in the receiving circuit.

In all Marconi calls there are three letters and all begin with an "M," except in the cases of German subscribers to the Marconi service, whose calls begin with a "D." About eighteen months ago the navy also inaugurated a three-letter call system, as the similarity in many of the two-letter calls was causing great confusion. Now all its shore stations on the Atlantic coast have calls beginning with "NA" and on the Pacific with "NP," the ships' calls beginning with "NB," "NC," "ND," etc. The United Wireless stations for the most part use two-letter calls. Marconi operators use the Continental code exclusively, the United Wireless operators the American Morse, and the navy operators must know both.

Mr. W. R. Williams, manager of the Western Union Telegraph Company, Elizabeth City, N. C., writes: "I hope you will pardon this stock expression, but TELEGRAPH AND TELEPHONE AGE is 'Fine Business' which we all, even to the messengers, greatly enjoy."

Entertaining Chicago Telegraph Messengers.

On December 18, 1911, the messenger boys of the Western Union Telegraph Company in Chicago were given a vaudeville entertainment by the Young Men's Christian Association. Prior to the entertainment the Western Union Company furnished the boys with a substantial supper. They marched from the main Western Union office through the crowded down-town streets to the Y. M. C. A. building, headed by a brass band. There were 340 uniformed messengers in the parade, and as they marched through the streets they attracted much attention and elicited considerable applause on account of their general neat appearance, and manliness. Several of the boys carried a large banner reading:

"Western Union Telegraph Messengers.

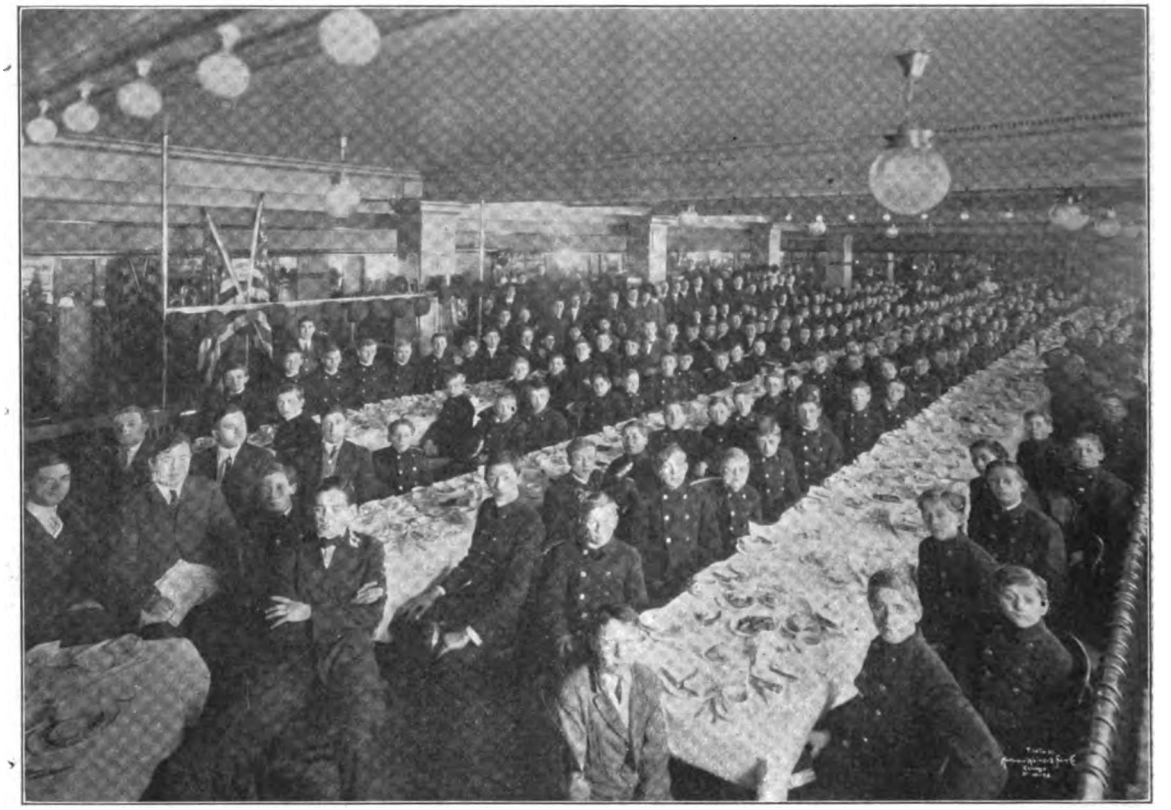
"Christmas Treat Given by Y. M. C. A. and the Western Union Telegraph Company."

During the supper, which was greatly enjoyed by the boys, the orchestra played popular airs and several "request" numbers, the messengers and all others present singing together.

Both the supper and entertainment were attended by the higher officials of the Y. M. C. A. and by the following Western Union officials: Mr. M. T. Cook, division commercial superintendent; Mr. W. J. Lloyd, division traffic superintendent; Mr. A. B. Cowan, district commercial superintendent, and Mr. John Fitzpatrick, district commercial superintendent.

Mr. Fitzpatrick is conferring with the Y. M. C. A. officials with a view to securing scholarships for some of the messengers and to devise ways and means of otherwise helping them.

The accompanying illustration shows the messengers at supper.



ENTERTAINING CHICAGO MESSENGERS AT SUPPER.

Economy and Efficiency in the Government Departments.

In a recent message to the Congress regarding economy and efficiency in the government departments, President Taft enumerates various subjects yet to be inquired into, including telephone, telegraph and commercial messenger service, electricity purchased and electrical equipment and supplies. "From what has already been ascertained concerning certain of these different objects of government expenditure," he states, "it is evident that large savings will result from such an examination."

Telegraphs and Telephones in Australia.—The government of Australia has appropriated $6,326,450 for extension of the telegraph and telephone services, and $81,757 for wireless telegraph stations.

Mr. W. S. Metzler, of the Canadian Pacific Railway Company's Telegraph, North Bay, Ont., in renewing his subscription for another year, writes: "You are always safe in renewing my subscription. TELEGRAPH AND TELEPHONE AGE is useful and interesting to me."

Government Control of Telegraphs in England.

The argument of postmaster-general Hitchcock and other theorists that the telegraphs in this country could be operated by the government at a profit, thus reducing taxation, is not supported by facts and experience in countries where the government controls the telegraphs. The experience of England is usually cited as an example. Everything there was promising at and before the beginning of government control, but in practice the theory did not work that way.

The London *Spectator* recently reviewed the subject and gave some plain facts in regard to England's experiences with the telegraph. The facts given are matters of record and they should be pondered by those who advocate government control. The *Spectator* characterizes the experience as a costly financial failure. It says:

"Forty-five years ago, in 1866, the proposal for the purchase by the government of the British telegraph lines was first advanced, and an allegedly conservative estimate set the cost at $11,500,000. It took nearly three years to complete the negotiations, and in 1869 Parliament appropriated $35,000,000 for making the purchase—nearly three times the original estimate; but in addition to that the government was called upon to pay the railway companies for their freehold interest in the telegraph equipment running along their lines, the right of way having been only leased by the telegraph companies; that meant another $20,000,000—so the acquisition of the business stood the British government $55,000,000. It was still predicted that within twenty years the net revenues would materially reduce the tax rates on the properties of the people. The disillusionment came quickly. For the first two years of the government operation there was a small net revenue, but after that the returns could not be made to meet the interest on the capital investment, and for thirty-nine years this enormous interest has been paid out of the exchequer—the pockets of the people. Then telegraph rates were reduced under the popular cry that reduced rates would increase the business and that increase would produce profits—but just the reverse was the result. The cost of maintenance and operation increased enormously under government ownership; and the revenues falling far below this and the upkeep and necessary improvements constantly calling for more money, the drain on the exchequer became increasingly heavy.

"When all these facts are taken into account—namely, the original capital which has never been repaid, the advances from Parliament upon which no interest is charged, and the annual deficiencies on working expenses—it will be found that the aggregate commercial loss to the country by the state purchase of the telegraphs is not less than $175,000,000. Nor can we console ourselves with the reflection that for this $175,000,000 the state has a valuable asset, for that asset, such as it is, involves every year on its working an additional loss of over $5,000,000. From a commercial point of view the purchase has been an unmitigated failure. To reply, as the advocates of state action invariably do, that the public has received compensation in the shape of a more efficient and a cheaper service, is plausible but unconvincing. For even if we make the large assumption that the service is better and cheaper than it would have been if it had remained in private hands, we are entitled to ask by what right the taxpayer is deprived of his money in order to subsidize persons who send telegraphic messages? The latter are a minority of the population; they are mostly well to do, and they are principally represented by two classes—purely commercial men, who look upon telegraphing as a business expenditure; and the racing fraternity, who certainly have no special claim to the charity of the taxpayer.

"The working cost per one thousand words telegraphed in Great Britain today is actually more than it was thirty years ago. The fatal incapacity of the British government to conduct a business enterprise has here been demonstrated beyond all question or cavil. It is to an experience like this that thousands of well-meaning reformers are seriously inviting the people of the United States today."

Pennsylvania Railroad's Telegraph School.

The Pennsylvania Railroad Company's school of telegraphy at Bedford, Pa., is equipped with the most modern appliances for teaching every branch of railroading with which a telegraph operator should be familiar. The library contains text-books on electricity in all of its branches, and is very complete. Students are also instructed in the use of the telephone in connection with telegraphy and the duties of the station agent, and taught to keep accounts.

An automatic sending machine with a transmitter that can be set at any speed has been installed to teach students to receive messages.

All graduates of the school are given positions on the Pennsylvania Railroad with the assurance they will have steady employment if they are faithful to their duties, and will be eligible for promotion to higher positions.

A careful selection of applicants for admission is made in order that they may fully meet the company's requirements. In the preparatory course all students are instructed and examined daily on the book of rules and in the graduate department practical demonstrations of train operation are given by means of a "miniature railroad."

Experienced instructors are employed in the school, and it requires from six to eight months to complete the course, according to the ability of the student to learn.

Any young man between the ages of seventeen and twenty-five years, having good eyesight and hearing, good health and a fair knowledge of the English language, mathematics and geography, is eligible for admission. Mr. Thomas Saddington is manager of the school.

Mr. R. R. Lamkin of Memphis, Tenn., in renewing his subscription, writes: "I thank you kindly for keeping TELEGRAPH AND TELEPHONE AGE coming, as it has become a necessity to me."

Mutual Investment Association, New York.

At the third annual meeting of the members of the Mutual Investment Association held on February 1, at 253 Broadway, New York, the following resolution was unanimously passed:

"Resolved, That the members of this association unite in expressing to Mr. Edward Reynolds, their treasurer, their admiration for the highly successful manner in which he has managed the association's affairs from the beginning, and voice their gratitude for the results accomplished not only during the past year, but during all of the time since the association was started. All understand and appreciate that these highly gratifying results are due to his intelligent and devoted interest in the association's affairs.

"Not only have we reason to feel pleased with the financial showing, but it is gratifying also to know that the sphere of the association's good work extends beyond its membership and that its operations have worked in a beneficent way for many others who are not members."

This resolution was beautifully engrossed and illuminated on parchment in book form and presented to Mr. Reynolds. The signatures of all the members appear on the pages, and the book is handsomely bound in soft leather. Naturally, Mr. Reynolds is highly pleased with this token of appreciation. Through his efforts, the association has grown to large proportions.

In his report to the members, Mr. Reynolds says, with reference to remedial loans, that there has not been a single instance of dissatisfaction with the association among any of those to whom loans have been granted.

In addition to encouraging the habit of systematic saving, the association assists worthy employes with loans in times of need at the rate of 6 per cent per annum, no bonus in any form being required.

"In making loans to employes," says Mr. Reynolds, "we have been governed entirely by our belief in their honesty. We never take an assignment on wages, thereby placing the borrower upon his honor. Perhaps the most gratifying feature of our experience is, that, notwithstanding the fact that we have made no attempt to protect ourselves from loss by assignment of wages, our 'bad and doubtful accounts' to date, spread over a period of three years, will not exceed $500. Of this one hundred dollars has been lost through the death of the debtor, and I am confident that $200 of the remainder will be collected.

"I have found no disposition whatsoever on the part of the borrowers to evade their obligations. We have treated them fairly and they have shown their appreciation of it by paying their loans. Some who have left us to go to distant parts and to the employ of other concerns have voluntarily paid up their debts, although we were not in a position to compel them to do so. We can afford to be optimists in the continuance of the business."

Mr. Reynolds' thought, time and labor are given to the association without compensation, and he has accomplished much good in behalf of the employes. Professional money-lenders find no encouragement among the Postal people, and they are practically unknown as such. Many employes who had questionable reputations have been taken in hand by Mr. Reynolds and lifted up to a higher plane of self-respect, and now they are men of high character.

The report includes some correspondence between vice-president and general manager Mr. E. J. Nally of the Postal Company and Mr. Frank Hedley, vice-president and general manager of the Interborough Rapid Transit Company, New York, on the subject of the loan-shark evil, which has been completely eradicated from the Postal service. Mr. Nally, in his letter, explains the details of the Mutual Investment Association's successful method of dealing with the problem.

The Railroad.

Mr. W. H. Wilmont, formerly division operator for the Pennsylvania Railroad at Belvidere, N. J., has been appointed assistant division operator on the newly organized Trenton division, with headquarters at Trenton, N. J.

Mr. G. C. Kinsman, superintendent of telegraph, Wabash Railroad Company, Decatur, Ill., has returned to his office after spending the month of January in Southern California where his family is passing the winter.

Continental Telegraph Company.—The Continental Telegraph Company, organized a few years ago, operates on the Chicago, Milwaukee & Puget Sound, Tacoma Eastern, Gallatin Valley and White Sulphur Springs and Yellowstone Park railways, comprising a total of 2,137 miles. The main line of the Chicago, Milwaukee & Puget Sound Railway, from Mobridge to Seattle, consists of three copper and three iron wires over the entire distance, and there are several additional iron circuits between various points.

Meetings of Railway Telegraph Superintendents.—A joint meeting of the Eastern and Western divisions of the Association of Railway Telegraph Superintendents will be held in Chicago on March 20. Mr. E. A. Chenery, superintendent of telegraph, Missouri Pacific Railway, St. Louis, Mo., is chairman of the Western Division and has charge of the arrangements for the Chicago meeting. A special meeting of the entertainment committee of the Association of Railway Telegraph Superintendents is called for February 16 in New York, when plans will be outlined and discussed for the entertainment of the members and their families who will attend the next annual convention which will be held in New York June 24. Mr. L. B. Foley, superintendent of telegraph of the Lackawanna Railroad, New York, is acting chairman of the committee during the absence of chairman L. S. Wells, superintendent of telegraph of the Long Island Railroad, New York.

The Turner Monument Fund.

The fund for the erection of a monument at Harriman (Turner), N. Y., to commemorate the sending of the first train order by telegraph, has been materially increased since the last acknowledgment by a contribution of $500 from Mr. Andrew Carnegie.

The fund now stands as follows: Previously acknowledged, $1,776.99; Mr. Andrew Carnegie, New York, $500; interest from Washington Trust Company, New York, $13.10; total, $2,290.09.

Telephone Train Dispatching in 1911.

(*Continued from page 87.*)

The following reports from railway telegraph superintendents, in addition to those published in our issue for February 1, have been received, showing what was done on their respective lines during 1911 in the extension of telephone train dispatching:

Mr. W. W. Ryder, general superintendent of telegraph, New York Central Lines, Chicago, Ill., says: "A considerable mileage of telephone train dispatching circuits has been installed during the past year, as well as some telephone circuits for the handling of way office messages. In detail, the situation at the end of the year on the various roads under my jurisdiction is shown in the accompanying statement. You will note a little more than two-thirds of the entire railroad mileage is now dispatched by telephone. It is our intention to make considerable further extensions of this service during the present year, particularly for way-message business, it being clearly evident there is as much improvement in the handling of this class of business by telephone as there is in the dispatching of trains."

TELEPHONE CIRCUITS ON NEW YORK CENTRAL LINES.

		Mileage.
Lake Shore & Michigan Southern Railway.	(Total)	1657
Dispatched by telephone		1602
Way office railroad messages by telephone		546
Telephone used exclusively for all way office messages		348
Michigan Central Railroad.	(Total)	1731
Dispatched by telephone		862
Big Four Railway.	(Total)	2391
Dispatched by telephone		1263
Way office railroad messages by telephone		109
Telephone used exclusively for all way office messages		69
Chicago, Indiana & Southern and Indiana Harbor Belt Railroads.	(Total)	351
Dispatched by telephone		351
Way office railroad messages by telephone		351
Telephone used exclusively for all way office messages		351
Lake Erie & Western Railroad.	(Total)	886
Dispatched by telephone		574
Toledo & Ohio Central and Zanesville & Western Railways.	(Total)	482
Dispatched by telephone		279
Lake Erie, Alliance & Wheeling Railroad.	(Total)	87
Dispatched by telephone		87
Dunkirk, Allegheny Valley & Pittsburgh Railroad.	(Total)	90
Dispatched by telephone		90
Telephone used exclusively for all way office messages		90
Cleveland Short Line and Lake Erie & Pittsburgh Railways.	(Total)	47
Dispatched by telephone		47
Telephone used exclusively for all way office messages		47

[The table shows a total railway mileage of 7,722. On 5,155 miles of road or nearly 70 per cent. of the total, trains are dispatched by telephone, and way office messages are handled by telephone on 1,560 miles. Compared with the figures of the Atchison, Topeka & Santa Fe system as given in the table published in our issue for June 16, 1911, the length of the telephone dispatching circuits on the New York Central Lines seems to slightly exceed that of the Santa Fe system, but inasmuch as the data of the two systems are not uniform an exact comparison cannot be drawn. General superintendent Ryder has always been a strong advocate of train dispatching by telephone and the results of his activity in this direction are shown in the record. In Canada, the Canadian Pacific Railway leads in the matter of telephone train dispatching. The figures given in the table published June 16, last year, show a total mileage thus operated of 3,952. This was increased during the year following. Mr. W. J. Camp, assistant manager of the Canadian Pacific Railway's Telegraph, Montreal, has also always been a firm believer in telephone train dispatching and is active in introducing the system over his lines.]

Mr. W. P. Cline, superintendent of telegraph, Atlantic Coast Line, Wilmington, N. C.: During the year 1911 the Atlantic Coast Line Railroad Company added 180 miles of wire to its telegraph system and made further provision for 210 miles which were in course of erection at the end of the year. Three hundred and forty miles of additional telephone circuit (metallic) for train dispatching and 275 miles of similar circuit for message work were put into service and at the end of the year 331 miles of telephone dispatching circuit and 331 miles of telephone message circuit were in course of erection. The superiority of the telephone in train dispatching service was demonstrated so clearly by the operation of the initial circuit established two years ago on this line that, notwithstanding no successful attempt has been made by this road (or, so far as the writer is informed, by others) to state the advantages in terms of dollars and cents, it was decided to equip that portion of the main line from Richmond, Va., to Jacksonville, Fla., with complete telephone facilities for each district, consisting of a dispatching circuit, a message circuit and a block circuit. The greater portion of this equipment was put into service during the past year and the remainder is rapidly nearing completion.

Mr. C. L. Lathrop, superintendent of telegraph and signals, Pittsburgh, Shawmut & Northern Railroad, Angelica, N. Y.: "The Pittsburgh, Shawmut & Northern Railroad has just completed a telephone train dispatchers' circuit from St. Mary's, Pa., to Brookville, Pa., 47 miles, strung with 210-pound copper and equipped with Western Electric apparatus, using six selectors and eight siding telephones. During 1911 forty miles of new pole line were built, covering an extension of the road south from Knoxdale, Pa., to Mahoning, Pa., which connects the new mines of the Allegany River Mining Company. This line is equipped with telephone service."

(To be continued.)

Modern American Telephony
In All Its Branches

THIS book, edited by Arthur Bessey Smith, E. E., assisted by a large corps of telephone experts, is just off the press. It is new, up to date, and covers every phase of the theory and practice of telephony, and will be found invaluable by engineers and students.

The book is pocket size, bound in black seal leather and contains about 800 pages and upward of 400 engravings and diagrams. The subject matter is treated in clear and simple style, and everyday problems are dealt with in a practical manner which will recommend this handbook to all members of the telephone profession.

Destruction of Telegrams, Etc.—According to a decision of the Interstate Commerce Commission a telegraph company is permitted to destroy all original telegraph messages transmitted by it at public tariff rates after having preserved them for one year after the date of the messages. Free messages, government messages at reduced rates, or any other messages at reduced rates, are not included in the order, however. These latter classes of business will be passed upon in a further order of the Commission.

Obituary.

Fred E. White, aged 54 years, an operator, died in North Adams, Mass., on January 30.

Edward L. Graul, aged 41 years, operator for the Philadelphia & Reading Railroad at Reading, Pa., died February 9.

Richard Powers, an old-time and military telegrapher, aged 71 years, well known in many sections of the country, died in New York on January 19.

W. S. Chapman, aged 69 years, an old time and military telegrapher and formerly secretary and treasurer and a director of the Central Union Telephone Company in Chicago, died in that city February 6. He entered the telegraph service in 1862 and was cashier for the United States Military Telegraph Corps, Department of Missouri, under Col. R. C. Clowry, until the close of the war. In 1879 he entered the telephone service.

Colonel Beverly W. Wrenn, aged 68 years, president of the Auto-Transportation Company, New York, and an old-time and military telegrapher, died on February 7. Colonel Wrenn was a telegrapher in the Confederate Army during the Civil War and after the cessation of hosilities filled many railroad positions in the South. He had been a resident of New York for several years and was identified with many business enterprises all of which were successful.

James A. Dunn, aged thirty years, formerly an operator, and son of Harry J. Dunn, an old-time telegrapher at 195 Broadway, New York, died February 8 in a sanatarium in Liberty, N. Y. For the past ten years Mr. Dunn, who was an expert banjoist, had played in vaudeville, and had toured the United States as well as many European countries. He begun his theatrical career at the age of 15 years and was known on the stage as James D. Polk. Deceased was 30 years of age and had a host of friends in and out of telegraph circles who will regret to learn of his death.

Telephone Train Dispatching on a Southern Electric Railway.

One of the electric traction systems of the South, the Piedmont & Northern Lines has placed orders with the Western Electric Company for telephone train dispatching equipment to be used on two of its lines.

The first of these, the Piedmont Traction Company, is to operate its cars over a twenty-four-mile stretch of line extending from Charlotte to Gastonia, N. C. There will be seven way stations located along the line as well as eight semaphores of the new Western Electric selectively operated type.

The second line is that of the Greenville, Spartanburg and Anderson Railway, which will install telephone equipment over approximately fifty-eight miles of road from Greenville to Greenwood, S. C. Eleven way station equipments and eight semaphores will be installed.

The equipment to be used is of the very latest type throughout. The selectively operated semaphore is a new development and is operated by the dispatcher by means of a selector key in the same manner that a way station is signalled. An "answer back" or audible signal informs the dispatcher when the semaphore has operated.

J. W. Young With the Kerite Company.

Mr. J. Warren Young has resigned his position as chief signal inspector of the Erie Railroad Company to take a position with the Kerite Insulated Wire & Cable Company, New York. Mr. Young was born in New York City on November 3, 1877, and entered the service of the Central Railroad of New Jersey in April, 1896, as signal maintainer's helper, remaining with that company until November, 1899, when he resigned to take a position with

J. WARREN YOUNG.

the Delaware, Lackawanna & Western Railroad as maintainer and inspector of signals. Later he went with the New York, Susquehanna & Western Railroad to take charge of its signal work. In September, 1904, he was appointed supervisor of signals of the terminal division of the Erie Railroad, and in November, 1905, was appointed signal inspector in the signal engineer's office, which position he held until January 1, 1907, when he was promoted to the position of chief signal inspector.

The Mecograph Premier.

Ten years ago the Mecograph was introduced to the telegraph fraternity as an improvement in telegraph transmitters, and since that time it has undergone eight changes for the better. The Mecograph Premier represents the latest development in this machine and is meeting the most exacting requirements. It is easily and simply adjusted and works all the time on good and poor wires alike, and in any kind of weather. The tension against the dash-and-dot arms is uniform at all times and is furnished by only one straight spring, and is regulated by a thumbscrew. The instrument has a great range of operation and the dots can be made as heavy as desired on the poorest of wires. This transmitting instrument has saved the day for many telegraphers afflicted with the "glass arm," and placed them in the first class as senders where, before, they were in the lower grades, on account of their affliction. It also lightens the strain upon normal muscles. The Mecograph Company, 321 Frankfort Ave., Cleveland, Ohio, will be glad to explain the merits of this instrument to all interested.

New Italian Post and Telegraph Building.—A new central post and telegraph office is being erected in Florence, Italy, at a cost of $386,000. The central telephone exchange will also be housed under the same roof.

LETTERS FROM OUR AGENTS.

LOS ANGELES WESTERN UNION.

An electrical class has been organized in this office and has a membership of thirty-six students. It meets every Friday night. Mr. G. C. Terry is president and Messrs. G. E. Palmer, T. W. Kane and P. G. Tompkins constitute the committee on instruction.

OMAHA WESTERN UNION.

Among recent visitors at this office were Messrs. J. C. Nelson, general superintendent; C. R. Fisher, district plant superintendent; E. E. McClintock, commercial district superintendent; B. L. Brooks, district traffic superintendent; W. C. Titley, division plant superintendent, and B. P. Meyers, chief operator, all of Denver, Col.; A. B. Cowan, commercial district superintendent, and M. J. Duggan, overland chief, Chicago, Ill.

Mr. J. S. Owens, chief operator, has returned from a tour of inspection in this district.

W. H. Smith, who had worked in this office for the past twenty years, died recently and was buried January 7.

The operating room in our new quarters in the Woodmen of the World Building [see page 68, issue of February 1] will be on the sixteenth floor. A feature of the room will be its wide aisles and strictly up-to-date equipment. It is claimed this will be the most modern telegraph office in the United States. The lease was closed through general superintendent J. C. Nelson, Denver, Col., and Mr. F. E. d'Humy of the office of the Engineer of Equipment, New York. The old office has been in the present building for thirty years and has outgrown its quarters.

District plant superintendent W. Salisbury has returned from Chicago, where he went on company business.

PHILADELPHIA POSTAL.

Mr. R. A. Barton has resigned as manager at Lancaster, Pa., to enter other business, and Mr. H. A. McCanna, manager at Lebanon, Pa., has been appointed to succeed him. Mr. McCanna is well known in Lancaster, having been previously connected with that office for many years under Mr. Barton. Mr. Claude Harkins, operator from Bethlehem, Pa., will succeed Mr. McCanna as manager at Lebanon. Mr. Ray H. Horn of the Western Union at South Bethlehem, Pa., will take up the duties as operator at Bethlehem.

Among recent visitors were Messrs. H. L. Krum and G. D. Wilkinson, both on business connected with the Morkrum printer.

Assistant manager A. E. Zintl was the recipient of many congratulations upon the birth of a son recently.

Mr. Frank Gallico of this office was recently married to Miss Madelenna Chicocelona. His office associates presented the couple with a handsome parlor suit.

The Telegraphers' Mutual Benefit Association, 195 Broadway, New York, enables telegraph and telephone employes to provide for their families life insurance in reasonable amounts, at a cost so low as to be within the reach of all. It has already paid beneficiaries of deceased members $1,650,000, at an average annual cost per $1,000 of about four cents a day, and has also accumulated $328,000 Reserve Fund securely invested, to provide against excessive cost in the future. Membership is easily acquired and cannot be invalidated during life for any cause except failure to pay the necessary mortuary calls.

TRANSMITTING MACHINES

I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to

James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

Proper Care and Operation of Storage Batteries.

The storage battery is probably the most efficient battery ever devised and for that reason many are led to conclude that no rules of importance govern the method of charging and discharging it.

In fact a prevalent impression exists that after the battery is once started it will take care of itself and yield all that its indicated capacity calls for. Such, however, is not the case.

Like every other electric device, a storage cell will yield its maximum output only under conditions which will permit the accumulation and discharge of energy to develop at a rate which is no greater than the material and elements which compose the cell can properly take care of. When this normal rate is exceeded there is necessarily a waste of energy, and because of such losses manufacturers of commercial storage batteries, particularly those of 40- to 60-ampere hour capacity, construct the cells on the basis of a normal 8-ampere-hour rate of discharge. For instance a cell of 100-ampere-hour capacity is expected to yield a current of twelve and one-half amperes for eight hours. The general impression is that this cell will also give out one ampere for 100 hours, twenty-five amperes for four hours, fifty amperes for two hours or any other value similarly obtained. Theoretically, it should do so, but practically, it will not do anything of the kind. The greater the drain is over the 8-ampere-hour rate, the greater will be the shrinkage of the full or indicated accumulation. In other words, the energy will be exhausted before the rated number of hours have expired.

Those regularly employed to charge storage batteries of course understand the situation, but laymen often subject the plates to a great strain by continuing to charge them for too long a time at or near the finish of the charge, at which time the wear on the plates is greatest, and also by renewing partly exhausted cells unnecessarily frequently.

The latter tendency is particularly prevalent with laymen who use storage batteries for the operation of automobiles and motor boats. They are so afraid that the battery will become exhausted some time while out on the road that it is the rule with some of them to "fill up" the cell by a recharge after one or two trips have been made, as one would a gasolene tank. The result of this action subjects the plates to unnecessary strain and wear.

For example, suppose we have a battery capable of running a car eighty miles on one charge. We then run it ten miles and recharge the battery, after which we run it thirty-eight miles more and again recharge it. Now give it a final run of say, twenty miles, and recharge as before; what is the result? A little figuring will show that the car has actually been run sixty-eight miles altogether, yet the battery has been recharged three times although the original charge was more than sufficient for the distance covered.

An expert informs the writer that he gets maximum results from his motor battery consisting of twenty-four cells by proceeding as follows: Begin recharging with a current of about nineteen amperes and maintain that rate until the E. M. F. reaches sixty-one volts. Then reduce the current to eight amperes and keep it there until the voltage, which dropped when the current was reduced, again reaches maximum. This method, it is claimed, minimizes the strain on the plates and also insures a maximum charge of the cells.

The time required to fully charge the battery, when, say two-thirds of its full capacity has been exhausted, he claims, is about three hours, with a current of nineteen amperes and from one and one-half to two hours with an 8-ampere rate. When seventy-five per cent of the charge has previously been used up about six hours' recharge will be required.

In case of an emergency where it becomes

Digitized by Google

necessary to obtain a quick recharge the starting current should not exceed fifty per cent of the cell's capacity; nor should one expect a very satisfactory recharge at that, under the circumstances.

It is a difficult task to determine just how much of a cell's capacity has been used up after many trips have been made, but one need have no anxiety concerning the remaining supply so long as the E. M. F. is above 1.7 volts per cell. When it reaches that value it indicates that about seventy-five per cent of the charge battery has been used. In fact a storage cell should not be recharged until the voltage drops to that figure.

In measuring the voltage the battery must be in active operation, otherwise the reading would be of no value whatever. A storage cell in almost anv degree of exhaustion would show nearly two volts if not working.

Telegraph and Telephone Patents.

ISSUED JANUARY 30.

1,015,768. Automatic Telephone Circuit and Repeater. To C. Adams-Randall, Augusta, Me.

1,015,769. Telephone Circuit and Repeating apparatus. To C. Adams-Randall, Augusta, Me.

1,015,770. Multiple Repeating Telephone System. To C. Adams-Randall, Augusta, Me.

1,016,617. Telephone System. To W. A. Fricke, Chicago, Ill.

1,016,670. Listening-Detector for Telephone Lines. To E. Burgener, Wellesley, and C. Burgener, Linwood, Ont., Canada.

1,016,699. Signaling Device. To R. H. Manson, Elyria, Ohio.

1,016,847. Terminal Plate for Telephone Desk Stands. To G. Nelson, New York.

Personal.

Mr. N. Hucker, the veteran telegrapher of Buffalo, has the sympathy of his many friends in the death of his wife which occurred recently.

Mr. R. Sardaneta, of the Federal telegraph service, Vera Cruz, Mexico, was engaged during December and January in installing wireless telegraph stations in the Quintana territory.

Mr. Kent Cooper has been appointed to fill the newly-created position of superintendent of traffic of the Associated Press, with headquarters in New York. Mr. Cooper will have entire charge of the leased wire service.

Mr. T. D. Lockwood, general patent counsel of the American Telephone & Telegraph Company, Boston, Mass., is in London where he will spend a few weeks. He will then take a trip through the Mediterranean and thence to Rio Janeiro, Brazil, and Buenos Aires, Argentine, before returning home.

Telegraph and Telephone Stock Quotations.

Following are the closing quotations of telegraph and telephone stocks on the New York Stock Exchange February 24:

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. H. A. Tuttle, president and general manager of the North American Telegraph Company, Minneapolis, Minn., accompanied by Mrs. Tuttle, spent the month of February in Nassau, Bahamas.

Mr. E. B. Pillsbury, general superintendent, New York, has returned from a three weeks' trip to Panama and the West Indies. He reports having received hospitable treatment from the cable officials at Havana, Kingston, Colon and Panama, and found the cable offices at each port to be fine examples of up-to-date cable stations, each one rendering service of the highest type of excellence as to speed and workmanship.

Mr. Edward Reynolds, auditor of the company, has returned to his office after a western trip, visiting many of the principal cities between New York and Minnesota.

Mrs. M. M. Davis, wife of Mr. Minor M. Davis, electrical engineer and chief engineer of telephones, New York, died at her home in Brooklyn, N. Y., February 16. The funeral services were held on Sunday, February 18, and were attended by all the officials of the company, from vice-president and general manager E. J. Nally, down. Much sympathy is expressed for Mr. Davis by his associates and friends.

Mr. N. I. Taylor, cashier of the Washington, D. C., office was a recent executive office visitor.

Mr. W. J. Fowler, manager of the Cedar Rapids, Iowa, office has been appointed manager of the Lincoln, Neb., office, vice W. W. Morrison transferred to the managership at Oklahoma City, Okla.

Mr. M. J. Supple, operator in the Cedar Rapids, Iowa, office has been advanced to the managership to fill the vacancy caused by the transfer of Mr. W. J. Fowler to Lincoln.

Mr. C. W. Soules of the Boston staff has been permanently transferred to the Providence, R. I., force.

Digitized by Google

Manager J. A. McNichol and cashier J. H. Wilson of the Philadelphia office, recently visited Washington on company business.

This company has completed its underground installation at Binghamton, N. Y.

This company's new office at Newark, N. J., was opened for business on February 25.

W. I. Capen, Fourth Vice-President Postal Telegraph-Cable Company.

Mr. Welcome I. Capen, whose appointment as fourth vice-president of the Postal Telegraph-Cable Company, New York, was announced in our issue for February 16, has for nearly four years occupied the position of general superintendent of plant with headquarters at the same point. His wide experience in executive and construction work eminently fit him for his new position.

Mr. Capen was born at Brattleboro, Vt., July 25, 1854. He has been in the telegraph service all of his business life, his record beginning as a messenger boy at ten years of age, in his native place,

W. I. CAPEN,
Fourth Vice-President Postal Telegraph-Cable Company, New York.

with the Vermont, Boston & Montreal Telegraph Company. Later he became an operator for the same company, afterward entering the employ of the Western Union, and in turn serving many of the old opposition companies, eventually reaching the managership of the Automatic Telegraph Company at Baltimore, Md., retiring therefrom when that company passed under the control of the Atlantic & Pacific. Subsequently he served the Western Union at Cincinnati, Ohio, as wire chief, resigning to accept the managership of the Baltimore & Ohio office in that city. His appointment as manager of the Postal Telegraph-Cable Company at Cincinnati, began his connection with that company. His abilities were early recognized, and from Cincinnati he went to Indianapolis, Ind., there to become a superintendent of his company, and in April, 1906, was promoted to the general superintendency of the western division of the company with headquarters at Chicago.

Magnetic Club Spring Dinner.—The spring dinner of the Magnetic Club will be held at Moquin's, on Fulton Street, New York, on April 24. Hon. William A. Prendergast, Comptroller of the City of New York, will be present as the guest of honor, and will address the Club. The St. Denis hotel, on Broadway, which has been the meeting place of the club for many years, is to be torn down to make way for a modern business structure.

Postal vs. Western Union.—The Postal Telegraph-Cable Company has filed a complaint with the Interstate Commerce Commission against the Western Union Telegraph Company alleging discrimination and unreasonable charges by the Western Union on messages transmitted part way by the Postal Company and then necessarily turned over to the Western Union for further transmission to points not reached by the Postal Company. This involves the same question as to interstate messages that was decided recently by the Public Service Commission of New York State in favor of the Postal in regard to interstate messages.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Messrs. T. W. Carroll, assistant to the general manager, New York; H. C. Worthen, general superintendent, Atlanta, Ga.; L. J. Maxwell, district superintendent, Jacksonville, Fla., and J. P. Edwards, special agent, Atlanta, Ga., were in Havana, Cuba, recently on company business.

Mr. W. E. Athearn, engineer of equipment, New York, is in Havana, Cuba, on company business.

Among recent executive office visitors were: Mr. H. C. Worthen, general superintendent, Atlanta, Ga., Mr. J. C. Calvert, district superintendent, Richmond, Va., and the following superintendents of the American District Telegraph Company: P. G. Kern, Southern Division, Louisville, Ky.; R. C. Baker and G. McGann, Western Division, Chicago, Ill., J. M. Maddox, Pacific Division, San Francisco, Cal., and F. V. Sackett, engineer, Chicago, Ill.

Mr. M. E. Barrett, superintendent of construction of the American District Telegraph Company, Chicago, has been transferred to New York in a similar capacity.

Mr. Emil Zilly, manager of the marine observatory of the Western Union Telegraph Company, at Sandy Hook, N. J., was married to Miss Isabella Pape at Long Branch, N. J., February 15.

Mr. L. P. Grover, traffic chief at Helena, Mont., has been promoted to be chief operator at Salt Lake City, Utah, vice J. W. Dudley transferred to Omaha, Neb., in a similar capacity, vice J. H. Owen, promoted.

Senator W. L. Ives, of the operating department at 195 Broadway, who has been in the hospital for some time has recovered sufficiently to be able to leave the institution.

Digitized by Google

Mr. W. G. Peebles has been appointed manager of the Atlanta, Ga., office, vice W. J. Francis appointed district manager of the second district.

Mr. J. S. Calvert, district superintendent, Richmond, Va., announces the appointment of managers in his district as follows: R. N. Pfaff at Blackville, S. C., vice H. L. Dorrity; D. F. Barnett at Suffolk, Va., vice J. W. Stephenson, Jr., who leaves the service; Chas. Knott at Manning, S. C., vice Miss M. S. Bookman; Mrs. M. R. Thompson at Statesville, N. C., vice C. J. Jones who leaves the service.

A conference of district commercial superintendents was held at 195 Broadway on February 17, at which matters of general interest to the service were discussed. Those present were Messrs. E. M. Mulford, division commercial superintendent, New York, and the following district commercial superintendents: C. W. McKee, St. John, N. B.; C. F. Ames, Boston, Mass.; W. A. Sawyer, J. F. Nathan and E. P. Griffith, New York; J. W. Reed, Philadelphia, Pa.; A. C. Terry, Pittsburgh, Pa., and A. C. Kaufman, commercial agent, New York.

The Telephone.

Birthday of the First Telephone Patent.—February 14 was the thirty-sixth-anniversary of the filing of the first Bell telephone patent.

Speech by Telephone.—At the banquet of the Yale Alumni Association in Chicago, February 17, each diner listened to a speech by President Hadley of Yale University, transmitted from New Haven, Conn., by telephone.

Receiver's Sale of Illinois Tunnel Company.—The receivers for the Illinois Tunnel Company of Chicago, which operates the automatic telephone system in that city, have been ordered by United States Judge Kohlsaat to sell the property of the company on March 19.

Pacific Telephone & Telegraph Company's Report.—The annual report of the Pacific Telephone & Telegraph Company for the year 1911 shows revenues of $16,070,112, and expenses, including $3,217,000 for depreciation, as $12,607,838, leaving a total net revenue of $3,462,274. Interest and dividends on the preferred stock made a deduction of $3,276,647, leaving $185,627 earned on the $18,000,000 of common stock, or about 1 per cent.

Wireless Telephone.—It is stated that the national government has accepted the wireless telephone installations at Mare Island, Goat Island, Farallone Islands, Table Bluff and Point Arguello, Cal., and on two cruisers. Tests were made of the system, which is that of the National Wireless Telegraph & Telephone Company, between Mare Island and Point Loma, San Diego, Cal., a distance of 450 miles, and they gave satisfactory results. A dispatch from San Francisco states that conversation was successfully carried on with the U. S. transport "Sherman" 1,300 miles out on the Pacific, on February 15th.

New York Telephone Society.—At the meeting of the New York Telephone Society on February 19, Mr. S. M. Williams, manager press service, Western Union Telegraph Company, New York, made an address on the transmission of news by telegraph and telephone. The paper was discussed by Mr. W. J. Dealy, general superintendent Commercial News Department, Western Union Telegraph Company, New York; Mr. A. S. Hibbard, advisory capacity executive department, of the American Telephone & Telegraph Company, New York; Mr. Gerard Swope, of the Western Electric Company, New York; Mr. B. Gherardi, engineer of plant, American Telephone & Telegraph Company, New York, and Mr. George C. Allen, superintendent of plant, New York Telephone Company, New York.

Telephone Merger in St. Louis.—The Bell Telephone Company of Missouri was merged into the American Telephone & Telegraph Company at a meeting held in St. Louis, Mo., February 20. The new directors chosen are Union N. Bethell, vice-president of the American Telephone & Telegraph Company, New York; E. D. Nims, vice-president of the Missouri & Kansas Telephone Company, St. Louis, Mo., H. J. Pettengill, president of the Southwestern Telegraph & Telephone Company, Dallas, Tex.; C. H. Wilson, general superintendent Long Distance Lines Department, American Telephone & Telegraph Company, New York, and F. H. Hamilton, secretary and treasurer of the Frisco Railroad.

The Cable.

Mr. J. H. Carson, manager of the Anglo American Telegraph Company, London, England, sailed for home on the steamer *Olympic*, on February 21. He attended the dinner of the Morse Electric Club, New York, on February 17, and was delighted with the American hospitality on this occasion. He arrived in New York February 8. Mr. Carson's previous visit to America was in 1889.

Cables Between England and Belgium.—There are four separate cables between England and Belgium, two for telegraph and two for telephone, one of the latter being loaded. The lengths of the cables vary between 47 and 58½ knots. All telegraph circuits are worked on the Hughes type printing system. Through these cables London and Liverpool work direct with various German and Belgian cities.

Extension of Deferred Cable Service.—The Commercial Cable Company announces the extension of the deferred plain-language message service to Belgium, Egypt, the Sudan and the French colonies of Madagascar and Senegal. The Egyptian and Sudanese Administrations have declared English to be the language of the country of destination (L.C.D.) for their territories. The British Administration announces that the language of country of destination (L.C.D.) for any British Dominion is English, but for the Straits Settlements and the Malay States, the Malay language may be used instead of English and for the South African Union the Dutch language may be used instead of English.

Digitized by Google

The Central and South American Telegraph Systems.—A recent number of the Panama *Star and Herald* contains an interesting description of the development of the Central and South American Telegraph system, which was projected and carried out by Mr. James A. Scrymser, president of the company. Manager G. W. Miller, of the company's Panama office, also gave an interesting description of the operation of laying submarine cables.

New Panama Office of Central and South American Telegraph Company.

The new offices of the Central & South American Telegraph Company in Panama, are located in one of the most imposing buildings in the city. The floor space occupied is equivalent to 5,000 square feet. The office is separated from the public waiting room by a counter surmounted by iron lattice work. The manager's private office is at the left of the main entrance, and the arrangement of the quarters is entirely up-to-date, everything, including apparatus and fixtures, being of the most modern design.

Messages are sent direct from Panama to New York, without relaying, the new office being connected directly with the company's main office at 64 Broad St., New York.

The staff of the Panama office consists of Messrs. G. W. Miller, superintendent, W. Butterfield, E. Berg, F. Wright, L. Dyer, J. Milne, W. King, E. Clare, C. Canter, T. Yates, A. de Souza, J. Taylor, J. Clarke, A. Beecroft, E. Lassen, J. Alvarado, and E. Rees.

The headquarters of the Central & South American Telegraph Company are at 66 Broadway, New York, Mr. Robert L. McCann being the general manager.

Dinner to Mr. J. H. Carson.

Mr. Theo. N. Vail, president of the Western Union Telegraph Company gave an informal dinner in honor of Mr. J. H. Carson, manager of the Anglo-American Telegraph Company, London, England, at the New York Yacht Club on February 16.

Besides the host and guest the following gentlemen were present:

Messrs. Newcomb Carlton, J. B. Van Every and G. W. E. Atkins, vice-presidents; Belvidere Brooks, general manager; A. R. Brewer, treasurer; E. Y. Gallaher, auditor; S. M. Williams, manager press service; Rush Taggart, general counsel; G. M. Yorke, engineer; R. E. Chetwood, engineer of construction; Henry A. Bishop, director, Western Union Telegraph Company, New York; G. G. Ward, vice-president and general manager Commercial Cable Company, New York; James A. Scrymser, president, and R. L. McCann, general manager, Central & South American Telegraph Company, New York; Clement Lee, superintendent Direct United States Cable Company, New York; E. C. Sweeney, traffic manager, French Cable Company, New York; F. H. Nicholls, acting superintendent, Anglo-American Telegraph Company, New York; J. J. Carty, chief engineer; B. Gherardi, engineer of plant, and J. G. Waterson, engineer of traffic, American Telephone & Telegraph Company, New York, and Mr. R. T. G. Tangye, London, England.

A few remarks were made by Mr. Carson and all present drank to his health.

Rapid Cable Service.

In our issue for February 16, reference was made to the visit to this country of Mr. J. H. Carson, manager of the Anglo American Telegraph Company, London, England, and it was stated in that connection, that Mr. Carson's forte was the rapid handling and transmission of messages.

In an interview with Mr. Carson on the subject of fast work, we obtained some interesting facts from that gentleman. He produced statements showing the volume of stock exchange business passing over the Anglo American Cables when the markets are excited, and the number of messages exchanged in a few hours between members of the stock exchanges in New York and London. Cable capacity of 1,000 messages an hour is placed at the disposal of these exchanges, other cables, equipped with Wheatstone apparatus, being reserved for other classes of traffic.

A table showed the number of messages sent by certain firms, mostly between 3 and 8 p. m., London time (10 a. m. and 3 p. m., New York time), September 25-28, 1911. The total number of messages exchanged during these four days was 11,865, the highest number in one day being 3,208, and the lowest, 2,869.

"This," said Mr. Carson, "is probably the most rapid telegraphic service in the world, the time occupied in transmission being, in the majority of cases, less than one minute. The first sender, for instance, was able to correspond with New York, a distance of 4,000 miles, at the rate of over 130 messages an hour, and other senders a lesser number."

Obituary.

Robert Moses Talbot, a member of the United States Military Telegraph Corps, died at Cleveland, Ohio, on February 17.

Augustus G. Davis, aged 78 years, a well-known old-timer and manufacturer of electrical apparatus at Relay, Md., died recently at Elkridge, Md. He settled in Baltimore in 1870. He established the first telephone exchange, and operated the first electric car in that city. He was a cousin of Professor Morse, and was a forty-niner of the telegraph.

Miss Mary Mallen, sister of Mr. D. F. Mallen, assistant manager of the operating department, of the Postal Telegraph-Cable Company, 253 Broadway, New York, died on Friday, February 16. Miss Mallen was a frequent visitor at the conventions of the Old Time Telegraphers' and Historical Association and was well known and highly esteemed among a wide circle of friends and acquaintances.

Digitized by Google

John T. Joyce, who died at Buffalo, N. Y., on February 1, was born at Oswego, N. Y., seventy-one years ago. He was an old-time telegrapher and a member of the United States Military Telegraph Corps during the Civil War in the department of the Tennessee. After the war he studied law, and was a member of the legal profession in Buffalo from 1867 to 1889, when he was appointed pardon clerk at Albany for the state, which position he occupied until he retired two years ago.

Radio-Telegraphy.

Mr. Jack R. Irwin, the well-known wireless telegrapher, is now in charge of the Wanamaker wireless station in Philadelphia, Pa.

Wireless Convention Ratified. — The governments of Portugal and the Argentine Republic have ratified the Berlin radio-telegraph convention of 1906.

The Wireless Treaty Reported to the Senate.— The United States Senate Committee on Foreign Relations on February 21 authorized a favorable report on the radio-telegraph treaty.

Wireless from Flying Machine. — What is thought to be the first radio-telegram sent from a flying machine was transmitted by Horace Kearney at Oakland, Cal., on February 14.

Navy Wireless Telegraph School.—A bill has been introduced in Congress authorizing the establishment of a wireless telegraph school at the League Island Navy Yard, Philadelphia, Pa. An appropriation of $175,000 is asked for the purpose.

Wind Power for Wireless. — The power required to operate the three wireless stations at Curaçao, Dutch West Indies, is supplied chiefly by wind power. When there is not sufficient wind, which occasions are rare, gasoline engines are used.

Wireless in Portugal.—The Portuguese government has signed a contract with the Marconi Wireless Telegraph Company for the establishment of wireless service in that country. Stations will be erected at Lisbon, Oporto, Sao Miguel in the Azores, Funchal, Madeira, and at St. Vincent, Cape de Verde Islands.

Wireless Weather Reports.—The Marconi Wireless Telegraph Company of America has arranged with the United States Weather Bureau to exchange with the Weather Bureau at Washington, weather reports dispatched via steamers, for reports as to the weather conditions prevailing at the coast stations in the United States.

Wireless in Uruguay.—The War Department of Uruguay has completed an extensive installation of wireless stations connecting the Government palace, the residence of the president, the military posts, and the vessels of the navy. The instruments are of German make, and the installation was made under the direction of a Danish engineer.

Compulsory Wireless in Spain.—A bill has been introduced in the Spanish Cortes providing that after January 1, 1913, passengers will not be allowed to embark at Spanish ports in vessels not provided with wireless telegraphy. The maritime authorities are in each case to give an authorization after certifying that such apparatus is in good working order. This regulation is also to be obligatory on foreign vessels which touch at Spanish ports.

Wireless News-Letter to Isolated Islanders.— Postmaster-General Pelletier of Canada is arranging to send a weekly news letter by wireless to the inhabitants of the Magdalen Islands, in the Gulf of St. Lawrence, who are cut off from the world all through the winter months. The letter will be 1000 words long and will be sent at the expense of the Dominion Government. The news will be sent to the clergy who will read it at the close of the Sunday services. It will be written and read in French, which is the language of the people.

Wireless Telephony Between Germany and Canada.—Herr Kiebitz, of the German Postoffice Department, has, it is reported, successfully carried on telephonic communication between Berlin and Canada, by means of Hertzian waves through the earth, no aerial being employed. The impulses are transmitted by means of a special generator giving 100,000 cycles per second. The wires connected to the transmitting instrument are carried to two plates imbedded in the earth at a definite distance apart equal to one-half wave-length of the electric waves employed.

Germany to America by Wireless.—The wireless station at Nauen, Germany, has been improved recently and is now able to communicate direct with America, according to a Berlin dispatch. The station has an operating range of between 3125 and 3750 miles. The main tower is 650 feet high and is surrounded by thirteen other masts each 128 feet high. There are 450 German wireless stations under the control of the national postoffice department, but they are not permitted to handle commercial traffic; they are used for military and experimental purposes only.

Wireless Station at Pittsburgh.—Plans are being prepared for the installation of the most powerful wireless-telegraph station in the country outside of those in seacoast cities, in connection with the completion of the new building for the departments of mechanical and electrical engineering at the Carnegie Technical Schools, Pittsburgh, Pa. The equipment will be up-to-date in every particular, and it will be possible to communicate with the wireless stations on the Atlantic seaboard. A course in wireless telegraphy will be added to the curriculum in the department of applied science in addition to the classes in telegraphy and telephony.

Wires Cut by Meteorite.—The telegraphic apparatus in connection with the signal station at Finisterre was destroyed on January 25 by the fall of a meteorite.

Annual Report of Mackay Companies.

The annual report of President Clarence H. Mackay of the Mackay Companies, for the year ended February 1, states, in the opening paragraph, that the companies were never in better condition physically, financially or in the efficiency and enthusiasm of the staff.

The gross income of the telegraph and cable companies in 1911 was almost exactly the same as that in 1910 when it was the largest in the history of the company. The expenses, the report states, have increased principally by the higher wages paid to the skilled operators and other employes.

Referring to the night letter service the report reads:

"A 'night letter' service was inaugurated by the Western Union Company two years ago. The Postal Telegraph Company is giving this kind of service but is not seeking it. Careful study of its cost to the telegraph company as compared with the average toll received, convinces your trustees that it is carried on without a profit and probably at a loss. The night letter originated in France. It has been in use in that country for several years. The results there correspond with our estimate of it here. They have been unsatisfactory."

The Postal Telegraph Company declined to adopt the "day letter," although recognizing the fact that it was really a cut rate for long telegrams. "The Postal Telegraph Company's objection to it," the report continues, "is partly the same as to the night letter. It encourages a wasteful use of words and slows down the service by reason of the time required for its transmission. It is unprofitable in itself and detrimental to the regular traffic. This would have been fatal to the very fast service which the Postal Telegraph Company believes is the proper object of a telegraph company."

Referring to the reduction of cable rates on plain language cablegrams the report says: "The Commercial Cable Company does not regard this as a new source of traffic. It does not expect that the traffic will be either large or profitable. This expectation is borne out by the returns to date. The reduced rate is proper because there is a large class of persons of limited means whose needs of the cable service is only occasional, and who have no "codes" to compress their messages. They will find the new cable rate of advantage, when in times of stress or domestic affliction their need of cable communication with friends abroad is urgent.

"As a general proposition, however, reductions in present cable rates cannot be expected. Cablegrams are necessarily expensive. The cost of providing the means of transmission and of operating the means of transmission is so great as to preclude the possibility of cheapness. The mercantile community by the use of highly specialized 'codes' compress into a few words a mass of necessary and important matter and the expense is part of the merchant's operating expense and is taken into account in his transactions. The net cost per word is extremely small."

The relations of the Texas Postal Company to the Western Union-Bell Telephone interests are then referred to, owing to which the trustees of the Mackay Companies decided to extend the Postal Telegraph Cable Company's land lines throughout the territory of the Texas Company, "which has been done with phenomenal speed," the report states. "A first-class line has been built from Wichita, Kan., down through the State of Oklahoma and the State of Texas, through Fort Worth, Dallas and Houston to Galveston, nearly a thousand miles. Another line has been built from Baton Rouge, La., westward to Houston, Tex. Still another line is rapidly approaching completion from a point opposite Memphis, Tenn., to Little Rock, Ark., and Dallas, Tex. Connection has been made with Austin and San Antonio, Tex. Numerous spurs and branch lines have also been completed. The result is that that vast territory has been covered with a network of Postal lines and wires, and competitive service is now given in the full sense of the word. "With the completion of that system," the report continues, "the receipts of your land line system from telegraph business to and from that part of the United States are increasing rapidly and those receipts are no longer divided with a connecting company, as was formerly the case.

"Among the extensions and improvements commenced by the Commercial Cable Company during the past year is the change of its cable landings adjacent to New York City, from Manhattan Beach to Far Rockaway. This was rendered necessary by reason of the United States Government proceeding to dredge for harbor purposes at the point where the cables landed at Manhattan Beach. The changing of these cable landings from Manhattan Beach to Far Rockaway, it is expected, will be completed in the course of a few months. The Commercial Cable Company has completed the removal and enlargement of its terminal facilities in London."

"As to the telephone situation," Mr. Mackay states, " your land line system proposes to work out a comprehensive plan, by which it will string heavy copper wires on its poles in any part of the country, where independent telephone companies care to lease telephone circuits between cities and towns, and where such wires will be useful to your land line system for telegraph purposes, in case any of such independent telephone companies should discontinue such leases by reason of their being purchased by Bell telephone interests. Considerable progress has already been made in this direction, thereby utilizing the space on the poles of your land line system, and at the same time bringing in substantial revenue, and rendering aid and assistance to the independent telephone companies."

Postmaster-general Hitchcock's scheme for government acquisition of the telegraph lines in this country is thus referred to:

On January 15, 1912, the Postmaster-general of the United States announced that in his opinion the Government should purchase all the telegraph lines in the country and operate them through the Post Office Department. This announcement has not met the approval either of the President of the

Digitized by Google

United States or of the American people. It undoubtedly would involve sooner or later the taking over the telephone lines also, the same as has happened in Great Britain, and this in the United States would mean the incurring of a national debt of something over two billions of dollars, the present value of the telegraph and telephone lines, to say nothing of necessary extensions which are required in the telephone business from year to year at an appalling rate. The Postmaster-general's plan has met with little public response.

"The Mackay Companies has no debts," continues the report. "Its outstanding preferred shares ($50,000,000) have not been increased during the past five years. Its outstanding common shares ($41,380,400) have not been increased during the past seven years. No bonds, notes or stock have been issued and no debts incurred during the year and yet there has been substantial growth of your ocean and land line systems. During the present year important extensions and improvements to your system will be made on land and sea.

"The income of the subordinate companies of the Mackay Companies is greater than is required to pay the dividends of The Mackay Companies, but its policy is to obtain from its subordinate companies only enough money to meet those dividends. The physical properties of the subordinate companies are maintained in excellent condition. All reconstruction is charged to operating expense. All extensions and improvements have been paid for from annual receipts, including the new lines in Texas and adjoining states. No debts have been incurred. Your trustees feel that your system is in so strong a position that the stability of your investment is assured."

"The employes of the Commercial Cable and Postal Telegraph systems continue to invest their savings very largely in the shares of the Mackay Companies, their holdings being over two million dollars par value."

Following is the statements of accounts:

PROFIT AND LOSS ACCOUNT

RECEIPTS:		
Income from investments in other Companies		$4,128,490.61
DISBURSEMENTS:		
Dividends paid on The Mackay Companies Preferred shares	$2,000,000.00	
Common shares	2,069,020.00	
Operating expense, including Transfer Agents', Registrars', Auditors' and Trustees' compensation, office rent, salaries, stationery, engraving of certificates, etc.	32,091.72	
Balance carried forward	27,378.89

New Book on Wireless Telegraphy.

THE WIRELESS TELEGRAPHERS' GUIDE AND LOG-BOOK, by W. H. Marchant, of London, England, has just been issued by the Macmillan Company, and while it is not an exhaustive treatise on the subject of wireless telegraphy it will be found extremely useful by the practical wireless operator.

The first portion of the book is devoted to a description of the various pieces of apparatus which go to make up a radio-telegraph installation and to the principles which guide in their construction and erection, this being followed by a description of the leading systems of wireless telegraphy. The Brown telephone relay is well described and illustrated in one chapter, and in the succeeding chapters descriptions are given of methods of measurements; regulations and instructions for the working of ships and stations, together with other information of value.

A feature of the book is a set of log sheets at the back to enable the operator conveniently to keep a record of his voyages and working.

The book is illustrated in a manner that will be found very helpful to wireless operators, the diagrams being very clear.

The price of this book is $1.50 net and copies can be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Patent Treaty Ratified.—The United States Senate on February 7 ratified the convention for international protection of patents and other industrial property. The main provision reads as follows: "The subjects or citizens of each of the contracting countries shall enjoy in all other countries of the union, with regard to patents of invention, models of utility, industrial designs or models, trade marks, trade names, the statements of place or origin, suppression of unfair competition, the advantages which the respective laws now grant or may hereafter grant to the citizens of that country." The signatories are Great Britain, France, Italy, Germany, Austria-Hungary, Spain, Portugal, Norway, Denmark, Sweden, Mexico, Cuba, Brazil, Belgium, Netherlands, Japan, San Domingo, Servia, Switzerland, Tunis and the United States.

The best way to keep posted in telegraphic and telephonic progress is to read TELEGRAPH AND TELEPHONE AGE. Subscription price $2 per year.

Annual Dinner of the Morse Electric Club.

The Morse Electric Club of New York held its annual dinner on the evening of Saturday, February 17, at the Hotel Savoy, and it was without doubt the most brilliant and successful event in the history of the club. The affair was made particularly notable by the presence of many of the highest officials in the telegraph and telephone industries and the railroad and bench were likewise represented.

The dinner of last year was to have had as the guest of honor Mr. Theo. N. Vail president of the Western Union Telegraph and the American Telephone and Telegraph Companies, but as he was called to Europe on urgent business just before the time set for the dinner much regret was felt at his absence. At this year's dinner, however, he was present as the guest of honor.

Mr. Vail gave evidence of special delight at meeting so many of the officials and employes of the telegraph company, and seemed to enjoy the relaxation from business cares that the occasion afforded. He was also surrounded by many members of his telephone official family and was altogether quite at home among his telegraph and telephone people. He met personally many friends of his early telegraph days and interesting reminiscences of the olden times in the west were recounted—the days when there was only one overland telegraph wire and the buffalo and indians roamed over the prairies.

The beautiful banquet hall was brilliant in the light of hundreds of electric lamps and the scene during the dinner was indeed a charming one. There were 265 persons present and they were seated at twenty-eight tables, the tables having eight and ten places. The guests' table or dais, set across one end of the room, had accommodations for fourteen and in front of Mr. Vail's seat, at the centre, was a large bed of beautiful roses.

At each plate on the tables was a small silk American flag which was used in the place of a boutonnière and as the national anthem and other patriotic airs were sung these flags were waved overhead in time with the music.

The seating arrangements were perfect. Each person was provided with a printed list of names, opposite each name being a letter corresponding with the letter which marked the table to which the individual was assigned.

There was no confusion whatever in the seating and the reception committee is to be congratulated on the excellence of their arrangements in this regard.

After all were seated a flash light picture was taken and then the main feature of the evening's programme—the dinner—was undertaken. While the dinner was in progress excellent instrumental and vocal music was discoursed. A fine menu was served and enjoyed by all present.

Seated at the head table at the right of Mr. Vail who occupied the middle position, were, in the order named: Mr. E. T. Jeffery, president Denver & Rio Grande Railway, New York; Mr. C. H. Wilson, general superintendent, American Telephone and Telegraph Company, New York; Mr. H. F. Thurber, vice-president, New York Telephone Company, New York, and Mr. Angus S. Hibbard, advisory relation executive department, American Telephone & Telegraph Company, New York. On Mr. Vail's left were Mr. Belvidere Brooks, general manager, Western Union Telegraph Company, New York, (who acted as toastmaker,) Judge Victor J. Dowling of the Appellate division of the Supreme Court, New York; Mr. J. H. Carson, manager of the Anglo-American Telegraph Company, London, England; Mr. F. H. Bethell, president Bell Telephone Company of Pennsylvania, New York; Mr. Newcomb Carlton, vice-president Western Union Telegraph Company, New York; Mr. J. B. Van Every, vice-president Western Union Telegraph Company (and president of the club), New York; Mr. Charles Selden, general inspector of transportation and superintendent of telegraph, Baltimore & Ohio Railroad, Baltimore, Md., and Mr. Frank D. Giles of the Western Union staff, New York. Mr. Brooks acted as toastmaster and performed the delicate duties of that position with tact and skill.

At the conclusion of the dinner Mr. Brooks announced an intermission of ten minutes for social intercourse, but this feature proved to be so interesting that it was fully half an hour before the regular order was resumed.

In introducing the first speaker of the evening, Mr. Brooks expressed his pleasure in being able to welcome so many distinguished guests to this, the fifth annual dinner of the Morse Electric Club, and paid a warm tribute to president Theo. N. Vail, the guest of honor, and the chief of those loyal and earnest workers who are striving together under a community of interest in the service of the Western Union Telegraph Company. He then proposed the health of Mr. Vail which was pledged by all, standing, followed by three hearty cheers.

Mr. E. T. Jeffery, who has been present at every gathering of the Morse Club and is known as a witty and eloquent speaker, was then introduced and gave an outline of conditions in this country from the early pioneer days of sparse population and limited financial standing, yet with boundless possibilities and natural resources, through the stages of the development of transit and communication facilities, to the present time when the advantages of rapid transportation and intercommunication are enjoyed by all. During this period of growth, and in fact during the world's history there has been no such accessory to business development as the telegraph and telephone and president Vail stands at the head of those men of superhuman energy and unlimited confidence who have made possible the development of this most important factor in our country's success.

In touching upon the popular attitude toward the corporations and so-called trusts, Mr. Jeffery sought to show that such great combinations of business interests are a natural outgrowth of present conditions: that they are necessary to carry on the

Digitized by Google

enormous business of the country and that they make eventually for the benefit of all the people. A corporation is a cooperative society and means the progress and elevation of mankind in general in spite of what the demagogues say. Publicity, however, is the true foundation upon which the corporations will rest, when all the ramifications of these huge commercial enterprises will be open to the scrutiny of the public, whose good sense must be trusted to overcome their present antagonistic feeling.

Mr. F. H. Bethell spoke in humorous vein, declaring that, personifying the telephone interests, he felt somewhat like the lost child which had been brought home by the great father, but upon closer analysis believed that he was better entitled to be called the child that had stayed at home while his wandering brother, the telegraph, had been brought under the paternal roof, He added that there were perhaps other lost brothers waiting to be taken home by the great father.

Mr. Angus S. Hibbard, was here called upon to favor the company with some of his character songs. He gave two selections which met with loud applause.

Hon. Victor J. Dowling was the next speaker. He referred to his pleasant friendships with telegraph officials and his many acquaintances among the workers in the ranks, congratulating Mr. Vail on his ability and devotion of these men. This loyalty, he believed, has come from careful and sympathetic management, which promotes harmony and accord. The progress of the facilities for communication between man and man has kept pace with the growth of civilization and has been closely related with all other factors which have assisted the march of progress. The power of the press would be nothing without the improved facilities of the telegraph. Judge Dowling concluded with the expression of his hearty wish that the prosperrty of the telegraph company would be as great as all its officials and co-workers could wish, and congratulated the company on the spirit of good fellowship, loyalty and devotion which exists throughout its organization.

Mr. J. H. Carson was next introduced. He prefaced his remarks by a complimentary allusion to TELEGRAPH AND TELEPHONE AGE, saying that everyone present ought to be a subscriber, and that one could hardly read the paper for a year without finding something about himself in its columns. Mr. Carson took as his text the statement in TELEGRAPH AND TELEPHONE AGE for February 16 that rapid handling and transmission of messages was his forte. He then outlined the importance of the duties of telegraph men, dwelling upon the fact that the duty of rapid handling of messages devolved upon them and that upon this feature of the service rested the commercial prosperity of the country.

The evening's entertainment was brought to a close by the singing of the Ode to Morse led by Mr. Marion H. Kerner, the author.

The dinner of the Morse Electric Club may come but once a year, yet the memories of good cheer and good-fellowship carried away from one of these gatherings are more than sufficient to last until the next reunion comes around.

Following is a list of those present:

Albany, N. Y.—Van Zandt, W. H.

Atlanta, Ga.—Beck, L. H., Worthen, H. C.

Auburn, N. Y.—Wooster, J. B.

Baltimore, Md.—Albert, V. J., Anderson, E. A., Day, E. W., Selden, Charles.

Wireless Storm Detectors and Indicators.

The coherer and other wave detectors are very successfully used by Professor Turpain, of the Potiers University, France, in order to observe and record the electrical state of the atmosphere, says the *Electrical Review and Western Electrician*. A very practical use of his apparatus is to foretell approaching storms, and these can be observed as much as four hours before they arrive. At La Rochelle, France, Professor Turpain has erected a storm-observation post, and he uses an aerial based on the same principles as for wireless work. The aerial is mounted at a point about eighty feet above ground, and is brought down on a slope to a second point and thence into the station, giving a total length of 300 feet in all. In order to make a record of the waves he uses a coherer made up of a set of crossed steel needles, using four parallel needles having three others laid on them. The proper pressure is given by using small weights on the upper needles, and thus six contacts are obtained in series by this method. Such a coherer is mounted on a light board and underneath is mounted an electromagnetic tapper of the usual kind which strikes the board.

The first form of instrument has a storm indicator combined with a Richard aneroid barometer, and both give a record upon a common revolving drum. One cell of Leclanché battery is used with the coherer. Each of the latter's six contacts receive 0.25 volt per contact, which is found to be the best condition. The electromagnet has an armature carrying the tapper and also the light arm for the recording pen. In this way the atmospheric discharges are recorded on the drum parallel to the barometer record. The present instrument is designed to observe the frequency of the atmospheric discharges and from this there can be made deductions as to the electrical state of the atmosphere.

A second instrument is used by Professor Turpain in which the indications are more precise. The apparatus is a very sensitive one and needs special precautions to secure the proper mounting. It consists of the same coherer as already described combined with a sensitive milammeter, this being connected in series with the battery and tapper. With this instrument, the variations in the current through the coherer are recorded on the drum, and it gives reliable indications as to approaching storms. To this effect one observes the current variations up to the point where the cohering action takes place. When a storm cloud acts on the aerial, the successive states of cohering of the contacts allow a greater or less current to pass in the circuit, and these values are recorded on the drum. This action occurs until the atmospheric discharge becomes of such strength that it produces a greater cohering action and this is enough to bring the tapper into play. The coherer thus comes back to normal and the apparatus is ready to make a new record, and so on. The drum thus carries a series of such records following each other. As the instrument needs to be well protected from shocks, it is found best to suspend it by stout rubber bands.

Professor Turpain finds that the energy of the atmospheric discharges is best measured and recorded by another apparatus in which the bolometer principle is used.

International Telegraph Contests.

Mr. Ferdinando Geronimi, minister of posts, Rome, Italy, writes us that the great success of the Turin telegraph contest last year, during the exposition in that city, has suggested the advisability of holding annual international contests and for that purpose it is proposed to form an International Bureau at Milan, under the auspices of a national committee.

Most Northern Telegraph Line on American Continent.—What is thought to be the furthest north telegraph line on the American continent has just been completed by the Canadian government to Dunvegan, Alberta.

The Modern Way to Send a Telegram.—It is now common to see a person enter a telephone booth for the purpose of sending a telegram. The message is dictated over the telephone, the tolls deposited in the coin box and the transaction is complete.

Sending Chinese by Telegraph.

The following interesting story by Mr. Jeff W. Hayes, an old time telegrapher, is reprinted from the *Oregonian* of Portland, Ore., of which city Mr. Hayes is an old resident. Life in the early telegraph days was varied by the occasional initiation of an innocent "tenderfoot," in the Far West this form of diversion often taking Chinese characters as the bases of operation.

Prior to coming to Portland, Mr. Hayes says, "I had passed two years in Nevada in the high Sierra Mountains, and Arizona.

"'When the cruel war was over' among the Apaches in Arizona, I returned to San Francisco and accepted a position with the Western Union Telegraph Company in that city, as operator. I was assigned to the Portland wire at nights with young George H. Thomas, recently a candidate for Mayor of the City of Portland, at the northern end of the line.

"J. M. Baltimore was the Associated Press agent in San Francisco, exercising a sort of censorship over the news he received from the East. It was his duty to cull news that came over the overland wires sending anything that he thought would be interesting to the Portland people and performing the same office for the people south of San Francisco.

"On account of the inadequate telegraphic facilities the *Oregonian* could not publish a full telegraphic report and Mr. Baltimore's services were enlisted for the purpose of giving the *Oregonian* readers only the matter which would be of interest to them.

"I found Mr. Baltimore a very courteous and pleasant gentleman. He had, however, a joke that he endeavored to play upon any newcomer in the telegraph office.

"I was sending the *Oregonian* special and the Associated Press news to young Thomas over the only and lonely and dilapidated wire that connected San Francisco with Portland, when I espied a peculiar-looking sheet of report. A quick glance showed that it was addressed to the *Oregonian* and was dated Pekin, China, and started out 'Wing Foo Lum Ling Sam Wing,' etc., which was followed by a lot of Chinese hieroglyphics. As I glanced over this sheet I took a quick look at Baltimore, who was taking in the situation, and coming over to me asked if I was in trouble.

"'O, that is all right, Mr. Baltimore, I have lived on the Coast a few years—suppose you work that off on that young fellow over there in the corner from Sacramento, Bert Worthington,' I got five minutes' relief and Worthington sat down in my chair. Mr. Baltimore handed him a short special for the *Oregonian* and the next item on tap was the one dated Pekin.

"Worthington studied over the item, turning the sheet up and down, diagonally, and crossways, finally calling Mr. Baltimore to ask what this meant. The press agent asked if he couldn't send Chinese characters by telegraph and Worthington said he couldn't. Another operator who was in the joke came in to send the item. He elaborated on the wire all the Chinese lingo he had ever heard, using such expressions as Sam Ling, Tate Bott, Fat Ching, Fat Duck, Wing Sing, etc. George Thomas, at the other end of the line, was making spasmodic efforts to 'bk bk bk.'

"Worthington retired to the Sacramento wire and I resumed sending to Portland and all was serene.

"That evening in the sanctity of our room I told Worthington of the joke that we played upon him and he was eager to see it worked off on some other newcomer, which, of course, was done.

"I left for Portland shortly afterward and Mr. Baltimore soon followed and we were steadfast friends for many years. Bert Worthington also left San Franscico for Sacramento, where he took up the study of railroad business, beginning at the bottom.

"The results of his efforts can be shown in the success he has achieved. Three years ago he was appointed general manager for the Harriman lines in Oregon and Washington, which he resigned to accept the position of general manager and vice-president of a railroad in the middle West."

Sound Not Transmitted by the Telephone.

Many people think that when they speak over the telephone that the transmitter, battery and wire in some way carry the voice to the ear of the listener. This is not the case. The transmitter and the battery are a sort of miniature transforming station in which the vibrations of the air caused by the sound of the voice are caught upon the diaphragm and turned into electrical energy. As the diaphragm vibrates in front of the pole piece of the transmitter it may assume many shapes. The vibrating areas and the nodes or non-vibrating lines are at one time star-shaped, at another like the spokes of a wheel; they are generally geometrical figures, but the various forms of vibration cause varying pulses of electrical current flow to traverse the wire. At the receiving end the varying electrical flow attracts the diaphragm so as to cause, in similar sequence, the geometrical figures to be formed by it, and thus give out the very tones of the speaker's voice. What traversed the wire was not sound but current, and the ear piece or sounder re-transformed this energy back into the form of sound.

Hobbies of Well-Known Men.—The New York *Times* of February 18, published an interesting article entitled, "Well-known Men with Hobbies—and Proud of It." Mr. Theo N. Vail, President of the American Telephone & Telegraph Company and of the Western Union Telegraph Company, is a member of the Hobby Club of New York, his hobby being farming. Many other well-known men are members of the club.

Tracing Stolen Wire by Bloodhounds.—A lot of copper telephone wire was stolen recently from a pole line in St. Louis, Mo., and by the aid of a couple of Russian bloodhounds the theft was traced to a junk dealer.

Telegraph and Telephone Age

Entered as second-class matter, December 27, 1909, at the Post-Office at New York, N. Y., under the act of March 3, 1879.

Published on the 1st and 16th of every month.

TERMS OF SUBSCRIPTION.

One Copy, One Year, in the United States, Mexico, Cuba, Porto Rico and the Philippine Islands . $2.00
Canada 2.50
Other Foreign Countries 3.00

ADDRESS ALL COMMUNICATIONS TO
J. B. TALTAVALL, - - - *Publisher*
253 BROADWAY, NEW YORK.
T. R. TALTAVALL, Editor.
R. J. WEEKS, Manager Advertising Department.

CABLE ADDRESS: "Telegage," New York.
Telephone: 6657 Barclay

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

March 1, 1912.

President Taft Not in Favor of Government Ownership.

President Taft on February 22 sent a special message to Congress in which he positively disapproves Postmaster-General Hitchcock's recommendation that the telegraph lines be acquired and operated by the government. He believes in the principle of permitting private enterprise to carry on public utilities under due regulation as to rates by proper authority. This view of the situation is the one held by many prominent authorities as the most satisfactory way of dealing with the subject. It is really in the nature of a compromise in safeguarding the interests of the operating companies and the public, Government ownership of public utilities is not compatible with the principle of American government and the wisdom of the American people can generally be counted upon to do what is right at the right time. President Taft objects to government ownership of the telegraph because it would greatly increase the body of public servants.

A high compliment is paid to the management of the telegraph companies. Mr. Taft states that he does not believe from the evidence at hand that the telegraph properties could be managed any more economically or any more efficiently, or that the government could furnish service at any lower rate than the public are now required to pay by private companies.

All-Night Telegraph Offices in Small Towns.

It is remarkable how many villages there are in the United States which demand all-night telegraph service, and yet how rarely any of the inhabitants thereof find any use for it when they get it. Such demands usually arise from the urgent necessity of an individual to send a telegram in the middle of the night and he finds the telegraph office closed. Then an agitation among the other villagers is aroused and finally pressure is brought to bear upon the telegraph company to keep its office open. Such a thing as there being a reason for not keeping the office open never occurs to them. The fact is many such all-night offices are kept open at considerable cost to the company with no adequate returns for the service. In many instances the records show that not one message a month is offered for transmission after 9 p.m.. and yet the companies are asked to maintain all-night service in places where the business does not warrant it.

It is a difficult task to make the average villager believe that every other one of his neighbors is not sending telegrams at some hour of the night, even if he has no particular use for the service himself.

The Error of Self-Satisfaction.

Is the standard of intelligence among the rank and file of the telegraph service deteriorating? This may seem a strange question to ask, and yet few individuals can answer it satisfactorily. We regret to state, however, that the indications are that it is not as live a force as it should be.

The average operator of today does not realize or feel the necessity of increasing his knowledge along the lines that yield him his living. We do not make this statement altogether from personal knowledge and observation; many of our agents report the existence of this state of things in their respective localities, and these reports are of sufficient number to lead to the belief that the attitude is quite general.

Of course, there are many ambitious employés all over the country who eagerly seize every opportunity to learn more about their business, and they are to be commended; they are the ones who will succeed in life.

One great trouble with many of the younger men who have ambitions to occupy higher positions is that they will not make any effort to improve themselves intellectually so that they can fill such positions. Some, in their earlier years, yearned to become operators, and now they are operators, they are possessed with the belief that there is nothing more to learn. In some cases a few years' experience brings them to the realization of their error. There is hope for such, and they generally cut loose from the deteriorating influence of such belief and live in a more progressive atmosphere. But the man who will not learn, because, as he imagines, there is nothing more to learn beyond what he already knows, is in a sad plight.

Young telegraphers of today have every opportunity to rise in their profession; educational facilities are unlimited, and there is abundant encouragement and aid for those who wish to forge ahead. The first thing to do is to forget self and keep before the mind the object for which one is striving, then work hard for its realization.

Conservation.

Americans, as a class, are notoriously prodigal. The country is so rich in natural resources that the people have never, until late years, been brought to realize that there is a limit to nature's bounty, and that the sources of supply of natural products are being rapidly depleted.

The subject of conservation has loomed up in large proportions in the business world, and men in all lines of activity are beginning to realize that economy must be practiced in all things, and there is a general movement in this direction.

Conservation in little things is as important as in large things and much attention is being given to this subject at the present time.

The articles under the head of "Conservation Talks," which we begin publishing in this issue, will no doubt be read with interest by those who have the matter at heart. They are timely, and Mr. Higgins seems to have a good grasp of the subject. He points out the importance and necessity of preventing waste of materials, and in various ways conserving resources.

Telephone Service in England.

The London *Electrical Review* says:

"Since the transfer of the National Telephone Company's undertaking to the Post Office, there has been a singular outburst of complaints against the service in the public press, and it is freely asserted that it has greatly degenerated in efficiency. Specific instances of delay in connection and other faults are quoted, and a Telephone Users' Association has already been formed for the protection of the subscribers.

"We have," the article continues, "throughout consistently opposed the absorption of the company's system by the State, holding that efficiency and progress were more likely to be achieved by the former than the latter, and that the multiplication of civil servants was a grave error. Our attitude on this question is unchanged, but we cannot help feeling that the present agitation is grossly unfair to the Post Office. Be it remembered that the staff, the operators and the apparatus so recently taken over from the company are, with few exceptions, absolutely the same as under the old régime. Are we to believe that the Government service is so demoralizing that within one month the system has been reduced to a state of chaos, and that the operators have become utterly indifferent to the efficient performance of their duty? Surely this is an incredible and unworthy suggestion.

"We have for years used both the National Telephone Company's service and that of the Post Office, and while we have certainly found the former quicker and more satisfactory than the latter, we have not detected the slightest difference between the service in December and that given in January. It is no better—but it is no worse.

"It is, we believe, generally admitted that State service, like municipal service, is not conducive to the display of energy and smartness on the part of the employés; we do not wish to cast aspersions on the character of a large body of our fellow-citizens, but the fact is notorious, and is the inevitable outcome of the conditions of service, in which, as a rule, reasonably good conduct and a moderate output are sufficient to enable an employé to remain on the establishment for life; but we cannot suppose that in one month the habits of years can be changed, and that the company's staff has lost its keenness so quickly. In common fairness, at least a year should be given to the Post Office to show its mettle; the present attacks can only be ascribed to political or other extraneous motives."

Wireless Bill.—The bill introduced in the United States Senate by Senator Nelson of Minnesota, forbids any person, corporation or company within the jurisdiction of the United States to use or operate any apparatus for radio-communication as a means of commercial intercourse among the States or with foreign nations, or upon any vessel of the United States engaged in interstate or foreign commerce, or for the receipt of these messages, the effect of which extends beyond the exclusive jurisdiction of the State or Territory of origin or where interferences will be caused thereby with messages from outside, except under and in accordance with a license granted by the Secretary of Commerce and Labor. Violation of the bill is made a misdemeanor, subject to a fine of $500, suspension of the license and forfeiture of the apparatus. The bill is being sharply opposed by the wireless interests in the country particularly because it practically puts all the power in drafting regulations, etc., in the hands of the Secretary of Commerce and Labor.

A B C of the Telephone.

There are several excellent books on the telephone and its practice, but all men do not know the rudiments of the telephone. It is well, therefore, in order to gain an understanding of this instrument, as in everything else, to begin the study at the beginning. The telephone is no harder to know than any other electrical device and it becomes extremely fascinating on better acquaintance.

A B C of the Telephone is a good book for the student to start with. It explains the subject in non-technical language and the main facts connected with the telephone industry are stated in a clear and simple style. Although it is elementary in character it covers the whole subject of telephony so comprehensively and completely that after a careful study of the book the student will have a good working knowledge of the instrument and its many uses. The book is rendered particularly valuable by reason of the great many illustrations, each one of which tells a story. It has 350 pages and nearly 300 illustrations. The author of the work is Mr. James E. Homans and he is a master of the subject.

The price of this book is $1.00 per copy and copies can be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Course of Instruction in the Elements of Technical Telegraphy—X.

(*Copyrighted.*)

(Continued from page 111, February 16.)

[We began in our issue for October 16 the publication of a course of instruction in technical telegraphy. The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and is divided into chapters, following one another in logical order.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases, and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.]

Gravity Battery.

The Gravity cell is generally used in this country for telegraph purposes, and, since it is easy of access to all our students, a brief description of it will suffice.

The copper plate is at the bottom of the cell, and is in three pieces, riveted together in the middle, forming a kind of star in appearance. The zinc is usually the shape of a crow's foot, and is hung from the rim of the glass jar.

About three pounds of bluestone (copper sulphate crystals) are placed in each cell, on top of the copper plate, and the cell filled up with water until the zinc is submerged.

Without entering into all the different chemical changes in the cell, we may remark that two distinct solutions are formed; one, a solution of copper sulphate, the other a solution of sulphate of zinc. If these two solutions were of the same specific gravity, that is if a pint of one solution weighed exactly the same as a pint of the other, a porous pot, or some such contrivance, would be required to prevent them mixing together; but the copper sulphate, being the heavier, remains at the bottom of the jar, with the other lighter solution over it. It is this difference in bulk-for-bulk weight that gives us the name, "Gravity Battery."

As the battery is not ready for use until a certain amount of zinc sulphate solution is formed, it is usually kept on short circuit—that is, with its two end leads joined together—for 24 hours, and should not be left open afterwards for any length of time.

The white flaky salts, which creep down the exterior of the cell, are called creeping or white salts, and being in reality evaporated sulphate of zinc, form a good conductor; so that, if allowed to creep unchecked, these salts will gradually make a path from cell to cell, and tend to short circuit part of the battery.

One of the best preventives against creeping salts is to cover the surface of the electrolyte with some good oil, made from petroleum. This will, besides remedying the creeping salts, protect the electrolyte from evaporation, and save the labor of adding water to the cells at frequent intervals.

Another method is to smear the upper edge of the cells with paraffin; this will remedy the creeping salts, but will not, of course, affect the evaporation of the electrolyte.

The copper solution in a cell in good working condition is a bright blue color; the blue changing to the color of water, as it nears the zinc. A cell with a pale or dirty brown colored solution, requires renewing.

A local gravity battery will usually last about five weeks; a main line battery, about ten weeks.

We have stated that all substances offer more or less resistance to a flow of current, so, as the current passes through each cell, the plates and solutions, of which the cell consists, must offer a certain amount of resistance, depending a good deal on the nature of the electrolyte, since the resistance of a liquid is much higher than that of a metal. This resistance is called the internal resistance of the battery.

The internal resistance of a Gravity, or Crowfoot (derived from the shape of the zinc), cell is about two ohms, and the difference of potential (Electromotive Force) a little over 1 volt (1.07).

As we have likened the voltage of a battery to the strength of the cyclist, we may as well notice other points of resemblance. Look at the physical condition of the cyclist when he lines up, fresh and with his full strength, to run a race. His strength before starting is due to his build and constitution; it is in no way affected by the length of the race before him or the speed he will maintain, although it of course diminishes in proportion to his exertions after he has started.

Similarly, the strength, power, force, potential, whichever you like to call it, of a battery is due to its build or the number of cells it contains, and its constitution, or the kind of cells used, but is in no way affected by the resistance of the circuit or the current flow, although as in the case of the cyclist, this power diminishes as the resistance of the circuit is overcome. It is, in short, the motive power which drives the current through the circuit against the resistance, and is only affected by changing the arrangement or number of the cells of which the battery is composed.

The Volt being the unit of pressure, the battery strength, or potential difference, is the magnitude of the pressure, expressed in volts.

NOTE.—Potential, Pressure and Electromotive Force, are synonymous terms in this course.

A correspondent has suggested that some examples of the application of algebra to practical problems in connection with our course of study of technical telegraphy, might be appreciated. We have therefore prepared a few typical examples, and invite any of our readers and students to make further suggestions with a view to aiding the student to master the problems encountered in the study of these lessons.

Digitized by Google

The formula:

$$C = \frac{E}{R}$$

is a familiar one to every electrician, but in its modern form it has become

$$I = \frac{E}{R}$$

I representing current (in place of the former C) E for electromotive force (E. M. F.) and R for resistance.

This expression is known as Ohm's law, and is read: "The current is equal to the electromotive force divided by the resistance."

Example:

Let the value of E = 150
" " " " R = 300

then performing the operation indicated

$$\frac{(E)\ 150}{(R)\ 300} = I = .5$$

hence .5 is the value of the current flowing in a circuit of 300 ohms resistance and with an E. M. F. of 150 volts.

In the formula:

$$I \times R = E$$

the E. M. F. is the unknown quantity. The expression, however, shows it to be equal to the resistance (R) multiplied by the current (I).

Using the same values as in the former example we have

$$I \times R = .5 \times 300 = 150$$

which is the value of the E. M. F.

In galvanometer measurements this rule is given:

To find the necessary shunt resistance to make the multiplying power of the shunt any desired amount, divide the resistance of the galvanometer by the multiplying power less 1.

The multiplying power is usually expressed as N + 1, then according to the statement the multiplying power less one is (N + 1) — 1 = N therefore N may be used as the divisor in the algebraic expression of the rule, thus:

$$R\ s = \frac{R\ g}{N}$$

R s representing the resistance of the shunt
R g the resistance of the galvanometer, and
N the multiplying power of the shunt.

Suppose we are using a galvanometer with a resistance (R g) of 1,200 ohms, and the multiplying power (N) of the shunt is 100, what must be the resistance of the shunt? Substituting these values for the letters in the formula we have

$$\frac{1,200}{100} = 12 = R\ s$$

12 being the resistance of the shunt.

In measuring resistance, etc., by means of the Wheatstone bridge four quantities are involved, corresponding to the four "arms" of the bridge, problems being expressed in the form

$$X = \frac{A}{B} \times C$$

in which A, B and C are the known quantities and X the unknown.

Example: What is the value of x when

A = 50
B = 100
C = 5,000

substituting, we have

$$\frac{A}{B} \times C = \frac{50}{100} \times 5,000 = \frac{250,000}{100} = 2,500$$

therefore the unknown quantity x is equal to 2,500, which is the answer.

Electrical power, expressed in watts, is equal to the product of the square of the current expressed in amperes multiplied by the resistance in ohms, or

$$W = I^2\ R$$

Example:

In an electrical circuit of 1,800 ohms resistance and in which a current of 15 amperes is flowing, what is the electrical power?

Substituting these values we have

$$15 \times 15 = 225 = I^2$$
$$1,800 = R$$

$225 \times 1,800 = 405,000$ watts, the answer.

This may be expressed in horsepower by dividing by 746, which is the number of watts in one horsepower.

$$\frac{405,000}{746} = 543 \text{ hp.}$$

To find the electrical work expressed in joules performed during a given time multiply the quantity of electricity expressed in coulombs (current × time) which has passed in that time by the drop of potential.

This rule expressed as a formula is

$$J = I \times t \times I \times R$$

I representing current in amperes
t = time of current flow
R = resistance
J = Joules

It will be noticed that the factor I occurs twice in this formula, and as it is multiplied by itself, we can shorten the formula slightly as follows:

$$J = I^2 \times R \times t$$

We have multiplied I by I, therefore this quantity is expressed as I^2 (read I square).

Example: In a circuit in which 15 amperes pass in 2 seconds, and with a resistance of 1800 ohms, what is the work done by the current?

According to the rule, $I^2 \times t \times R = 15 \times 15 \times 2 \times 1800 = 225 \times 2 \times 1800 = 810,000$. Therefore, 810,000 joules is the answer.

The rule for calculating the joint resistance of two wires, is as follows:

Joint resistance is equal to the product of the separate resistances divided by the sum of the resistances. This rule expressed algebraically is

$$R = \frac{a \times b}{a + b}$$

Digitized by Google

a representing the resistance of one wire.
b representing the resistance of second wire.
R = joint resistance.

Example: We have two wires, one with a resistance of 900 ohms and the other 1800 ohms, what will be the joint resistance when both are connected together?

Using these numerical values in place of the letters of the formula we have

$$R = \frac{900 \times 1000}{900 + 1000} = 473.6$$

and performing the operation we get 473.6 as the value of R, expressed in ohms.

(*To be continued.*)

Aluminum for Magnet Winding.—Aluminum is about one-fourth as heavy as copper, has a specific resistivity not quite three times as great, and naturally forms on its surface an oxide which has a comparatively high electrical resistance, so that for winding coils of this metal no other insulation is usually needed. Abroad advantage has been taken of these properties in making magnets and field coils of all kinds, although in America less attention has been given to such construction. Several thousand railway motors are reported in service in England using aluminum field coils. For winding work the natural oxide of the aluminum surface is thickened by a corroding treatment. Even the natural oxide presents good electrical insulation, but with the thickened coating practically no electrical leakage can be discovered. For wires up to No. 16 equivalent carrying capacity aluminum is declared to have considerable space economy over cotton-covered copper wire, while in sizes above No. 16 it occupies nearly the identical volume. The entrance of moisture to such an aluminum coil does not impair the insulation, but actually tends to improve it, since a thicker coating of insulating oxide is formed. This oxide is, of course, fireproof, and withstands high temperatures without injury. An American manufacturer of large lifting magnets is now preparing to build these coils with aluminum windings. Such a magnet can be constructed with about one-third the weight and the same ampere-turns and carrying capacity as the copper coil.—*Electrical World.*

Protection for Inventors.

The "Inventors' Guild" has sent a petition to President Taft complaining that the patent laws of the United States, as they have been built up, interpreted and applied, not only fail to accomplish their theoretical purpose, but they have come to be a means of robbing inventors and discouraging and suppressing the exercise of ingenuity. The Guild asks the President to use his influence to bring about desired reforms.

Mr. Thomas A. Edison, Prof. M. I. Pupin, Dr. Peter Cooper Hewitt and other inventors of prominence are members of the Guild.

Mr. Edison recently expressed himself on the general subject as follows:

"The worst thing about 1912 is the number of hoggish men it will have to tolerate—men, I mean, who are so greedy that they'll starve an inventor so hard he can't work. That's just what we suffer from now. The inventor can't produce. Why, there is no end—absolutely no end— to the things that 1912 could produce to make life easier and better and happier. But the inventors can't produce. They're starved down. The men that handle their inventions starve them. That's why the greedy men are the year's worst blight. That's why 1912 won't do anything near what it might be able to do in producing things for the world's good.

"What should we do this year? Jack up the man who produces—the man who works. That is, support the man and make his job easier. I tell you there is something wrong—deeply, sadly, fundamentally wrong—with our social system when so many greedy men ride the backs of the men who are the producers. The men whose opinions of 1911 I thought best of were the men who can produce. Jack up that kind of man. That's the year's best message."

Western Union Plant Conference.

On February 14 a conference of plant chiefs and foremen of the first district, Eastern Division, was held at the office of district plant superintendent W. J. Higgins in New York. Suggestions were made for a form to be used by linemen as a general reference table in connection with making measurements for faults with the new bridge-testing sets. With this method faults can be readily located to within a few hundred feet of the seat of trouble.

The matter of methodical and frequent inspection of lines was fully discussed, and, in this connection the benefits derived from the recent changes in linemen's duties on the Delaware, Lackawanna & Western and New York Central routes were fully gone into.

Mr. M. C. Allen, division plant superintendent, addressed the meeting and gave a very interesting and instructive talk on questions of line maintenance and co-operation between departments and department heads.

There were present at the conference: Messrs. H. F. Whetzle, plant chief, and J. G. McNerny, city foreman, Buffalo, N. Y.; W. H. Collins and F. H. Barth, plant chiefs, respectively, at Scranton, Pa., and Syracuse, N. Y.; A. G. Petitt, plant chief and G. R. Craft, district foreman, Albany, N. Y.; F. W. Barth, district plant chief, and S. L. Hayes, district foreman, New Haven, Conn.; B. H. Mallery, district foreman, Binghamton, N. Y.; G. H. Laing, district foreman, C. C. Lever, general wire chief, T. J. Smith, district wire chief, and H. C. Hayes, assistant district wire chief, New York, and T. E. Casey, chief clerk, M. J. Wallace, estimate clerk and F. J. Finn of superintendent Higgins' office, New York.

Railway Telephone Inspection.*

BY JOHN A. KICK.

When a considerable number of men unanimously agree on any subject the lines of reasoning must necessarily be so obvious as to leave little chance for an argument; and this is just the condition today in respect to train dispatching by telephone. There is no longer any chance for an argument as to whether the telephone is the preferable means for handling trains, but there is still room for much discussion as to its proper application; that is, the class of equipment and its maintenance.

Just as long as there are two or more kinds or types of selective signaling systems, transmission systems, and the various accessories thereto, there will be arguments pro and con as to the relative merits of the various systems and accessories, and as there will be arguments concerning the merits of the equipment, just so will there be arguments as to proper methods of maintenance; in fact there is not the least probability of a majority agreeing upon any one method of inspection and maintenance as being the one right one.

Some maintain that the inspection should be made by the station lineman in connection with his regular duties, no special schedule of timing these inspections being necessary; others that the regular man should do the inspection work at intervals not to exceed two weeks; others fixing the intervals at four weeks; and still some others claiming the method of having the regular linemen do the inspection work to be all wrong. Of those having special inspectors and maintainers very few agree as to the proper way in which these special men should handle the work. Further discussion is had as to the amount of territory which one man can satisfactorily handle, and when you consider the fact that the conditions are so widely different, there appear good reasons for the failure to agree, as that which is deemed satisfactory on an unimportant line or division cannot be accepted on an important trunk line system where every minute lost service means delays to a whole fleet of trains. However, there are several phases to the subject which I believe must be common to all; and those are, the thoroughness of the inspection, the ability of the inspector, and his outfit.

Unless an inspector looks carefully over the equipment on his territory, acquaints himself with the location and class of equipment, and generally informs himself as to the physical make-up of the plant, he will be unable to render high-class service.

As an example of the truth of the above statement, we will imagine a telephone reported out of service at any given point and the inspector instructed to get to that point and make repairs. What is the type of telephone at that point? Where is it located? Will he be able to make the repairs with the material in his regular kit? What are the surrounding conditions, and what and where is the trouble? If the inspector is perfectly familiar with all the details of the plant, he will be able to arrive at a conclusion at once, and will know that unless the trouble is out of the ordinary he can make the repairs without delay.

While at a test station recently I met the inspector for that territory, and in conversation asked him if there was a good job of soldering on the leading in wires on the office pole. He informed me that he had some time ago examined them and finding one joint which did not suit him he had resoldered it and that they were now perfect. Pretty good indication of a man being interested in covering all possible chances of trouble, and that he was going to keep just a few laps ahead of trouble.

During several general inspection trips over the lines, a careful observation of the methods of the inspectors proved very interesting. One man was found to be so busy as rarely to find time enough at any station to cover what he wished, and he was really finding and righting minor defects or possibilities of defects at every point, nothing appearing to escape his inspections. Another under practically the same conditions did absolutely nothing except enjoy a holiday spent in riding over the division on the inspection train. The first mentioned man was notified en route of a bell failing to ring at a point down the line and when approaching that station he got some dry batteries ready and in two or three minutes had the bell going. He had recently inspected the station and tested the batteries and knew that they were near the point of renewal, and correctly judged the location and remedy of the trouble.

An inspector was notified of the failure of a yard line due to one office being unable to ring any one at times, and going to this station and finding the circuit working o. k. left, notwithstanding the fact that the failures had been intermittent. The third trip to the trouble resulted in finding the circuit out of service upon his arrival, and after walking over the line and clearing a swinging cross the trouble was experienced no further. Just a case of failure to take the trouble to ask a few questions, the answers to which would have assured him he would find trouble if he looked in the right place.

Regardless of the number of the inspections there cannot be too much care taken to make them thorough and no details can with safety be overlooked.

The inspector here is a general telephone utility man who can be just as good as you like and the better he is the more you will be able to appreciate how indispensable his services are. Be he the regular station lineman or special inspector, a knowledge of the make-up of every piece of equipment and the circuit wiring is necessary to enable him to get quick and intelligent action at all times.

It is recognized that the proper way to learn

*From *Telephone Engineer.*

Digitized by Google

the make-up of a mechanical or electrical feature of the plant is to attempt as nearly as possible to get the designers' ideas in so constructing or arranging the apparatus or circuit. While the telephone is somewhat new to some of the railway linemen yet I believe with the help of wire chiefs and others able to explain there should be no serious difficulty in qualifying a majority of the linemen to serve as capable inspectors.

There has been some little argument as to whether the inspector need be able to climb and do outside work. While there are some places where the inspector ordinarily will not be required to do outside work, yet there can be little doubt that the man who can capably do both inside and outside repair work is the preferable man for the position, as in emergency cases he is available for either duty. As these men are trusted to work alone there can be little chance for other than a reliable man to succeed in giving good service and retaining his position, as the opportunities to kill valuable time are many and very enticing to the shiftless fellow who would rather ride over the road asleep in the cabin car than get out and go over his work.

In the inspector's outfit should be, first of all, a good serviceable test set, which must be always on the job, as it is the one best means for locating troubles between stations, being as well of much assistance in locating difficult troubles within the stations. An inspector without a soldering outfit is certainly handicapped and it would seem that he could not be expected to accomplish much unless provided with a good soldering torch and iron. Induction coils are small and at least one spare coil could be carried. In fact, I believe that a small kit containing about the following would fill all needs:

Test set, soldering torch and iron (small), one induction coil, one receiver (the head band type without the head-band), one push button (the type used in the transmitter circuit of the high-power transmission circuit), three or four of each kind of cords used, one pair long nose pliers, one pair side cutting pliers, one or two screw drivers, one small screw starting drill, a few assorted screws and tacks, a bit of tape solder and wire.

Of course, there are a few odds and ends of small stuff that the inspector will find serviceable, but the total weight of his kit will not be more than half the allotted weight carried by the soldiers in our army. The inspector does his traveling by train or motor car and really does little transporting of his kit by actually carrying it, so that a fair-sized kit is little or no handicap.

Novel Suit Against a Telegraph Company.—There are many ways for aggrieved citizens to get even with telegraph companies. A messenger boy on a bicycle in hurrying to deliver a message ran into a state official. The official's dignity and equilibrium were disturbed by the violent contact with the speeding messenger and he has sued the telegraph company for $5,000 damages.

ANSWERS TO QUESTIONS.

[In this department questions on matters of a practical character, and of general interest, will be answered. Questions intended for this department must be signed by the writer's full name—not for publication, but for identity. No attention will be paid to anonymous communications.]

(90) Q. Kindly answer the following questions through the "Answers to Questions" column:

(1) What is the "rule of three"?

(2) What is the "KR Law"?

(3) What are Kirchoff's first and second laws?

N. L. O.

A. (1) The "single rule of three" is a rule of arithmetic, and is the same as proportion. It is the process of finding from three given numbers the value of a fourth, to which one of them shall have the same ratio as exists between the other two. For example: If ten men can do a given piece of work in four days, how long will it take five men to do the same work. According to the rule of proportion this is stated as follows:

$$10 : 4 :: 5 : x$$

that is ten is to four as five is to x, the unknown quantity. This is solved by multiplying the "means," 4 and 5, and dividing by the "extreme" 10; thus we have

$$\frac{4 \times 5}{10} = 2, \text{ which is the value of x.}$$

This rule may be found in any arithmetic.

(2) Signals transmitted through long telegraph and telephone cables, submarine and aerial, are retarded by the electrostatic charge, and the time required to transmit a given number of impulses varies in proportion to the capacity (K) in farads and the resistance (R) in ohms of the cable, and is therefore proportional to K R. This is known as the K R law.

(3) Kirchoff's first law is stated as follows: In any branching network of wires the algebraic sum of the currents in all the wires that meet at any point is zero.

The second law is: When there are several electromotive forces acting at different points of a circuit, the total elctromotive force around the circuit is equal to the sum of the resistances of its separate parts each multiplied into the strength of the current that flows through it.

Mr. J. B. Hammatt, an old time telegrapher of Peoria, Ill., writes:—"I am always glad to receive the AGE because it keeps me in closer touch with the telegraph fraternity—the business I have followed for so many years. Through it I am often reminded of the struggles and final achievements of that grand old man, Prof. S. F. B. Morse, who, along with Mr. Thos. A. Edison and Dr. Alexander Graham Bell wrought wonderful things for humanity—the grandeur of which will never dim while time shall last. I am therefore thankful to you who has made it possible for the small sum required to enable me to participate in these semi-monthly visits of so good a friend as the AGE."

CONSERVATION TALKS—I.

BY P. KERR HIGGINS, OKLAHOMA CITY, OKLA.

Economic Efficiency and Waste Prevention.

Preachments are not effective unless accompanied by remedies. "Cut out the waste" is nonconstructive criticism and it would seem better to use the phrase or slogan—prevent the waste—which can only be done by cutting out lost motion.

Conservation must begin in the individual unit, either person or thing and thence upward, the medium used being education and system, and the hope of future conservation or prevention lies in the younger element of the telegraph and telephone fraternity. This truism has been demonstrated in religion, politics and fraternalism where the standard is raised through the young.

These same methods will apply to business. Any employe is considered old only when he has ceased to adapt himself to changing conditions, and it is not expected that these articles will prove interesting to any such. To the progressive telegraph and telephone employe the writer simply asks an unbiased consideration of the facts, remedies or methods as presented. These articles are intended to suggest some new practical ways to prevent waste.

The time of reckoning has come, and the future generation will be less wasteful than the past has been; thanks to the present agitation. Few employes realize that everything wasted is not only a tax upon the one who wastes, but on every employe of the company.

I could cite hundreds of cases of negligence and lack of supervision which have come under my notice, resulting in waste. Waste was prevented in an exchange by a rearrangement of the electric lights and using lamps of high efficiency, thus reducing the electric-light bill to one-third. Again, by purchasing the clippings of a printing office, having them padded and furnished to employes for scratch paper prevented the waste of printed stationery. Still another form of waste was prevented by closely supervising correspondence and by writing (where practicable) answers on the query letter, especially between departments and company exchanges; also by having stock letters on specific subjects requiring frequent use of similar reminders, etc. In going over plants we also find a large waste of material in engineering, material in many cases lying idle for years. Truly there is much need for "efficiency engineering." It is unfortunate that more time cannot be devoted to direction and less to supervision and it is the hope of the writer that the education of the future will develop this desired end. It can only be done by developing a higher standard of manhood, willing and ready to assume responsibility, and earnest and sincere in its production of an honest day's labor, then the wage problem will be more satisfactory since net revenue, instead of going to a few, can be distributed to the many.

Briefly, then, the following are a few of the many chances for waste which do not involve a change in method so much as more and better supervision and direction:

First—Closer supervision of supplies sold, used and leased. Second—A detailed postage account. Third—Elimination of dual telephone systems. Fourth—Failure to develop the idle plant. Fifth—Combining pole lines. Sixth—Utilizing lines to full capacity. Seventh—Federal regulation rather than state regulation. Eighth—Closer timing on toll messages. Ninth—Saving lost calls. Tenth—Economizing wasted circuit time. This latter is extremely important as it develops that the time usually consumed in setting up a toll-line connection is about four times as great as the actual time consumed in conversation and can be prevented by closer observation of toll messages by the traffic department. The possibility along these lines for higher and more economic efficiency is very great.

Considerable toll-line economy can also be gained by concentrating the toll business at toll centers and permitting only the most efficient operators to handle the long haul circuits.

The standardization of methods, material and stationery would be a great improvement, as it would prevent waste of time and material and raise the efficiency. Take the case of transposing and we find all kinds and methods used; each change means waste and loss of circuit use. Again, in ordering supplies we find the departments making out requisitions, often copied by the manager, or by the district manager and possibly by the supply department.

We build expensive copper circuits in an effort to increase our transmission efficiency and neglect our local transmission, allowing batteries to play out before giving them proper attention. As a rule no effort is made to give our long distance patrons better facilities then those who do no toll business. We grudge battery expense but put money into larger wire. Adjustment of receiver diaphragms is ignored resulting in poor transmission and the batteries sent out or sold are apparently made for cheapness rather than efficiency. It is advisable to pay more and get a reliable battery. Here is ample room for improvement.

In making up cost units a large waste takes place by having many people carry on this work, and frequently the figures are not what they should be. It would seem much better and more economical to have a statistician to compile the figures of the various departments for the general manager. The practice of constantly watching costs is wasteful; it should, however, be done frequently.

In the matter of filing, it would seem best to have an archive department, where all completed files could be kept. Where the division of labor does not warrant separation departmental work should be combined. This is not always done and results in waste of time.

Digitized by Google

A stenographic department would also (for large companies) be economic efficiency. This would give the general manager's office close supervision over correspondence, etc., which he does not now have. It is wasteful to allow plants to run down merely to make a good cost showing. The constant changing of employes is a great source of waste, and impairs efficiency, hence much care should be taken to select prospective employes and greater pains taken to educate them; usually they are "hired" and turned loose to perform their duties without any training or instruction. This latter is much easier than the slow process of selection and training.

Another source of waste is that new methods are constantly being tried out, put into use and fail for lack of following up to a successful end or proving that they will not work. The writer has known many cases such as this. The same ideas also occur to different people (in authority) at different places at the same time and we find experimenting going on along similar lines everywhere. If these new methods or ideas could be centralized, tried and passed upon at some central point, great waste would be prevented.

Telephone Pioneers of America.

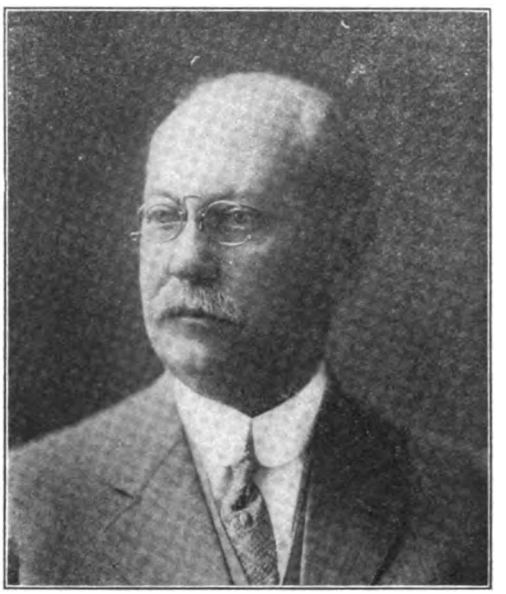
HENRY W. POPE.

Henry William Pope, secretary of the Pioneers of America, was born at Great Barrington, Mass., November 2, 1848. He was operator and manager for the American Telegraph Company at Great Barrington in the sixties, being transferred to the main office of the company at 145 Broadway, New York, in 1864. In 1866 he went with the United States Telegraph Company under J. W. Stover, manager, in the Old State House, Boston, Mass. This company was absorbed by the Western Union and Mr. Pope was transferred to the night force of the Western Union on which Mr. Thos. A. Edison was then employed as an operator.

Mr. Pope returned to New York in 1868 accepting the position of manager of the Atlantic & Pacific Telegraph Company's office in the Produce Exchange. Afterwards he became inspector for Pope and Edison, New York [firm of F. L. Pope and Thos. A. Edison] and chief operator of the private line department of the Gold & Stock Telegraph Company. He left this company to become assistant superintendent of the American District Telegraph Company under Geo. F. Durant in 1873 and general superintendent in 1875. In the spring of 1877, through Gardiner G. Hubbard, he became interested in the telephone and installed in the organ factory of Hilborne Roosevelt, Sixth Avenue and Eighteenth Street, New York, the first telephone ever placed in New York and from which developed the Roosevelt-Cheever system, later becoming the Bell system of the city. In 1878 he took up the promoting of telephone corporations and with his associates promoted both the Cleveland and Pittsburgh companies as well as others.

On November 1, 1879, Mr. Pope was appointed superintendent of the Bell Telephone Company of New York and was one of the appraisers of the telephone properties of the Bell and Western Union Companies which culminated in the merger of the interests and the incorporation of the Metropolitan Telephone & Telegraph Company, of which he became general superintendent. He was traffic manager of the Southern Bell Telephone Company in the nineties and acting general manager of the Bell Telephone Company of Buffalo during its reconstruction period.

Mr. Pope's successful joint work in bringing about the organization of the Telephone Pioneers of America, is not his first experience in this line. He organized and called to order the first National Telephone Convention at Niagara Falls, in September, 1880. He also organized the Mutual District Telegraph Company in New York and was its vice-president and general manager, and the Mutual District Messenger Company of Boston. He also organized and constructed a number of electric light systems, at Elizabeth, N. J., Morristown, N. J., and other places, together with the Citizens Illuminating Company of Brooklyn, the first to introduce electric light in that city, and of which he was president and general manager.



HENRY W. POPE,
Special Agent, American Telephone and Telegraph Co., New York, and Secretary Telephone Pioneers of America (1877).

Mr. Pope is now a special agent of the American Telephone & Telegraph Company with headquarters at New York.

Mr. J. E. Stevens, newly appointed district manager of the Western Union Telegraph Company, with headquarters at Greenville, S. C., writes: "I wish to congratulate you upon the success of your paper. It is indeed a publication of great value to all telegraph people, and I wish it continued success."

Wireless Telegraphy for Naval Purposes.

BY H. CLIFFORD STROUD.

In an interesting paper read at Newcastle-on-Tyne, England, abstracted in *The Marconigraph,* the author gives a bird's-eye view of the modern practice of wireless telegraphy and its application to present-day needs.

At the present time when crossing the Atlantic, says the author, one is never out of communication with land, and the passengers have issued to them the equivalent of newspapers, giving them the news of the world as soon as, or even sooner than, we read it in our morning papers.

The transmission of electric signals through the ether without the use of wires is effected by means of electric waves or oscillations, and we must consider (1) the generator of these ether waves, (2) the aerial which gives them the necessary send-off—*i.e.,* the radiator of the waves—and the similar structure for collecting them at the receiving station, and (3) the apparatus which detects the waves and makes the signals readable.

To commence with the generator of the electric oscillations, the first arrangement for their production was by means of the ordinary Leyden jar, or condenser, which consists essentially of two metal plates separated by some substance which does not allow an electric charge on one plate to discharge to the other. If the one plate is charged to a high potential with regard to the other, by means of an induction coil or otherwise, and then allowed to discharge itself suddenly through a spark-gap in the connection between the plates, it can be seen by means of revolving mirrors, that what appears to the eye to be a single spark is in reality a series of sparks. This is explained by the fact that the discharge overshoots the mark, or gives up too much of its charge, whereupon there is another spark in the reverse direction, which process occurs several times for each apparent spark.

The electric capacity of the condenser is large, the inductance of the discharge circuit is small. Now the time of oscillation of an electric discharge depends on both the capacity and the inductance.

The arrangement of the coil, condenser and spark-gap circuit is that commonly called the "closed oscillator." In it very little of the energy stored in the condenser is radiated, and so for the purpose of setting up oscillations in the ether it is useless. The simplest type of oscillator which is at the same time a good radiator is the "open oscillator." In its essential form it consists of a spark-gap with two wings of wire in the same straight line. The spark-gap is connected to the terminals of an induction coil. In such an arrangement there is no concentration of the lines of force—as is the case with the Leyden jar—and consequently the energy is rapidly radiated. The energy passes off in the form of electro-magnetic waves, which travel on indefinitely in the ether in all directions. It was with such apparatus that the first experiments in wave telegraphy were performed.

For laboratory experiments this is all that is required, but to transmit signals any distance it was found to be inadequate. In the first place, the length of the wings would have to be enormous to radiate the energy required to send any appreciable distance. The first improvement was to turn this oscillator on end, so to speak—*i.e.,* erect a long vertical wire with a spark-gap at the bottom, the other wing being cut short and connected to earth.

This was called the plain or Marconi sender. It has many latent disadvantages, however, the chief being that the capacity of this antenna or aerial must necessarily be small, and as the energy in the antenna is limited by its capacity and the length of the spark-gap—which cannot conveniently exceed half an inch—the radiation is bound to be rather small.

The improvement in wireless-sending apparatus which made long distance work a practical possibility was the introduction of what is called the "coupled circuits." The spark circuit is separated from the antenna, and a large amount of capacity is put into it, thereby obtaining great concentration of the energy with, at the same time, a small spark-gap.

The actual arrangement consists in connecting the aerial wire to a coil placed at the foot, forming an inductance, and thence to earth. Another coil is placed in close proximity to this, and contains the spark-gap and a condenser in circuit with it. These two circuits are called coupled circuits. The period of oscillation of the antenna circuit is arranged to be exactly the same as that of the condenser and spark-gap circuit.

This is the general elementary form of spark sender as in use at the present time. One modification is, however, sometimes made, and that is to make part of the inductance of the coupled circuits common to both.

The next thing is to understand the apparatus used for receiving the waves transmitted through the ether. As far as the circuits are concerned, there is no great difference between the sending and receiving, but, instead of setting up oscillations by means of a spark across a spark-gap, an instrument to intercept the minute oscillatory currents in the antenna flowing to earth must be suitably placed. A detector in common use is Marconi's magnetic receiver. This form of detector is used almost universally for naval purposes on account of its extreme reliability.

Another form which has recently come into general use is the Marconi-Fleming oscillation valve detector. This depends on the fact that when electric oscillations are arranged to pass between an incandescent metal filament (tungsten is now used) in the ordinary vacuum bulb, and a plate or cylinder sealed into the bulb, it acts like a non-return valve, only allowing the current in one direction to pass from the plate to the filament. In this form, as in all other modern forms of detector, a telephone is used to make these currents audible.

The next point of importance is the antenna or aerial wire. This is actually of the greatest importance, as in wireless telegraphy everything depends on the send-off which the waves are given by its means. The antenna may be one of many va-

Digitized by Google

rieties, and in many cases its shape depends not upon what would be the most efficient as upon ease of erection. To take a ship as an example, it would be impossible to erect an antenna of the umbrella type, but the antenna must be stretched between the masts. On land, however, these restrictions are to a large extent non-existent; and for land purposes there are umbrella, fan-shaped, cone, and many other varieties of antenna.

The earliest form of antenna was simply a long vertical wire supported by a mast, the idea being to reach as great a height as possible. In the modern forms there is a long vertical wire leading up to the main part of the antenna, and at the top the wires are arranged as circumstances permit, or, if there is any option, in the way which seems to be the most suitable. The umbrella-shaped antenna is, as its name implies, made in the form of the ribs and periphery of an umbrella.

In the design of an aerial the chief point is to get as much capacity as possible at the top, in order to give the waves a good send-off. On ships the support for the antenna must obviously be the masts, and so the shape is in general either T-shaped or inverted L-shaped, depending on whether the operating cabin is amidships or towards the bow or stern. The top part is usually made of six or eight wires held apart by cross-pieces, and in the form of a long cylinder, this is supported by porcelain insulators from the two masts, and two or more wires descend from it to the operating cabin through suitable insulation. This is the form of antenna usually seen on passenger boats equipped with wireless. There are, of course, modifications to suit the individual requirements of vessels, but in general construction they are much the same.

When the vessel had only one mast, as in the case of destroyers, submarines and some battleships, the form adopted is that of an inverted V, the antenna being stretched between erections at the bow and stern and supported by the mast in the middle.

It may be thought that the establishment of communication between two stations is dependent on having no obstruction in the direct line between the two antennæ. That this is not the case can be shown by a simple calculation. Let us suppose the two stations be 3,000 miles apart, as for transatlantic communication. The radius of the earth being taken as 4,000 miles, the heights to which the antenna would have to be erected would be about 330 miles. If this height had to be attained for communication over 3,000 miles, clearly wireless telegraphy would not advance very rapidly. This calculation, however, serves to show that the path of the waves is not in a straight line between the two stations, but must follow the circumference of the earth.

To have a good earth connection is of the very greatest importance, and this is, of course, very easy to obtain on board ship, all that is required being to connect to the hull of the vessel, which is in intimate contact with the sea, itself the best of earths.

As to the sending apparatus, the circuit can be tuned to any given note by varying either the capacity or the inductance of the circuit or both. The waves sent out from any oscillator travel on indefinitely in the ether until they strike some earth connected conductor, and if this aerial is tuned to the same frequency—*i.e.*, has the same wave-length—as that of these ether waves, this circuit will take up the oscillations in the same way as one tuning fork will respond to another of the same note, which has been made to vibrate. If, however, the aerial which intercepts the waves is not of the same frequency, the effect will be very greatly reduced, since it will only respond intermittently to the waves impinging on it.

The wave-lengths used in practice are as follows: The ordinary commercial wave-length for ships is 600 metres, which has a frequency of half a million oscillations per second. Between 600 and 1,600 metres is reserved by the Admiralty for warships in the British Navy, and for transatlantic work such wave-lengths as 2,000, 4,000 metres, or even greater, are used. The Marconi station sends constantly with 6,000 metre wave-lengths at its transatlantic station at Clifden, on the west coast of Ireland, sending to Glace Bay, Nova Scotia. It is found that for the same power messages can be sent longer distances with big wave-lengths than with small ones.

In a sending apparatus there is necessarily an interaction between the two coupled circuits. The primary circuit—*i.e.*, the one containing the spark-gap—sets up oscillations in the secondary circuit containing the antenna, and then the secondary reacts with the primary. This phenomenon can be demonstrated by suspending two similar pendula from a flexible support. If one is set swinging it transfers its energy to the other, which starts to swing, and in doing so stops itself; the second then starts the first in the same way, and so the energy is alternately transferred from one to the other. If the support is very flexible, corresponding to close coupling, two periods of vibrations are obtained; if, however, the support is less flexible, corresponding to looser coupling, the two periods become more nearly identical.

It is thus seen that the wave-length of the radiated waves consists of two components, one of which has a greater wave-length than that to which both are tuned, and the other smaller. Thus the total energy that is radiated is divided between the two wave-lengths, and neither is the same as that to which the coupled circuits are separately tuned This is largely overcome by weakening the coupling. To overcome this difficulty Mr. Marconi has adopted the quench spark.

If the spark-gap consists of very short sparks between cooled discs there is very large damping effect. By this method the primary oscillations are quenched by the damping after but one or two swings, and the secondary circuit continues to oscillate in a single period even with fairly close coupling, which, of course, gives rise to a wave of definite wave-length. In the development of this system a very large number of discharges are produced per second, and thus one very great advantage is obtained in the musical note produced in the telephone at the receiving station, which is distinct-

Digitized by Google

ive of the station transmitting, and is never confused by the operator with ordinary atmospheric disturbances.

Having thus dealt with the principles of wave telegraphy and the apparatus used for practical work, let us turn our attention to the purposes for which the science is used, and also those for which in the future it is hoped to be used. The foremost of these is the now almost universal fitting of passenger liners with wireless apparatus, so that at all stages of the voyage the ship is in continual communication with the shore and with other vessels at sea. This is so complete that on big liners a daily bulletin of the world's news is published.

The fact that already upwards of 3,000 lives have been saved at sea by the establishment of wireless communication is quite sufficient to show how extraordinarily useful a wireless installation can be on a ship. The use of wireless also for naval purposes is now universal, every ship in the British Navy being equipped.

An application of wireless telegraphy which it is probable will develop greatly in the near future is the "Radio-telegraphic compass." For this a directive antenna is used—*i.e.*, one by means of which signals can be sent in any desired direction, and also by means of it the direction from which any signals come can be determined. A certain number of fixed stations send out distinctive signals at intervals, the ship receives these signals, and thus its position is accurately determined. It is as yet only in its experimental stages, but, I am told, the company promoting the idea offers to fit vessels. It can readily be seen that such a method for determining the position of a ship would be extremely useful.

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. The review of Maver and Davis' book, "The Quadruplex," was completed in our issue for February 16, and the next book to be taken up and treated in like manner is "Electrical Instruments and Testing," by Norman H. Schneider, with chapters on testing wires and cables and locating faults, by Jesse Hargrave, a well-known and capable electrical engineer. These subjects will no doubt prove of great interest to students, as they are timely and important, and each student should have a copy of the book at hand in order to follow intelligently the study of the subjects under consideration.]

CLASSIFICATION OF MEASURING INSTRUMENTS.

Into how many classes may electrical measuring instruments be divided?

What instruments belong to the first class, and what kind of indications do they give?

What kind of instruments belong to the second class?

Name the instruments which give records of currents.

How can a simple galvanometer be made suitable for experimental work?

What is the effect upon the needle of a galvanometer when a current of electricity passes through the coil?

If the current is made stronger, what will be the effect on the needle?

If the direction of the current through the coil is reversed what will be the effect upon the needle?

[Study carefully the causes which effect these results as they are of the utmost importance in the study of electrical measurements. For instance, note the direction of the current through the coil; the effect of this current upon the N pole of the needle; the effect upon the N pole of a current flowing in the opposite direction. Clear knowledge of these facts is highly important in the work of making measurements.]

If a current of a strength of, say, one unit, causes the needle to deflect ten degrees, will a current of two units deflect the needle twenty degrees?

If it does not, give the reason why.

If a given battery strength gives a larger deflection on one galvanometer than upon another, the conditions of the test being exactly alike in both cases, what does the difference in deflection indicate?

How are the deflections of galvanometer needles measured?

Senor Mendez, Director-General Mexican Telegraphs.

Señor Mario Mendez, the new Director-General of Federal Telegraphs, Mexico, was born at Matamoros, Nuevo Leon. After studying in the college of San Juan at Matamoros, he entered the telegraph service at San Luis, Potosi. In 1897, he was made line inspector, and from this time his promotion was rapid. In 1898, he became first inspector in charge of a division, shortly afterward being made constructor of lines in the state of Yucatan. On the completion of the line between Chemax and Puerto Morelos, he received a message from the Secretary of War, congratulating him on the successful establishment of this important line.

Señor Mendez next held a position in the first section of the Director-General's office, where he rendered important services, being promoted successively to the positions of inspector of the second division and inspector-general of all telegraphs. From the latter position, he was promoted to that of chief of the central office, and on January 4, of the present year, he was made Director-General of Telegraphs.

Mr. G. C. Felton, manager of the Western Union office at Laredo, Tex., writes:—"Thanks for keeping my subscription alive. The AGE always looks good to me."

President Taft Disapproves of Government Ownership of Telegraphs.

In a special message to Congress on February 22, President Taft expresses his disapproval of Postmaster-General Hitchcock's plan for the government ownership of telegraph lines. Mr. Hitchcock's recommendation is left in his report which accompanies the President's message. Mr. Taft says in regard to it: "There is only one recommendation in which I cannot agree—that is one which recommends that the telegraph lines in the United States should be made a part of the postal system and operated in conjunction with the mail system. This presents a question of Government ownership of public utilities which are now being conducted by private enterprise under franchises from the Government.

"I believe that the true principle is that private enterprise should be permitted to carry on such public utilities under due regulation as to rates by proper authority rather than that the Government should itself conduct them. This principle I favor because I do not think it in accordance with the best public policy thus greatly to increase the body of public servants.

"Of course, if it could be shown that telegraph service could be furnished to the public at a less price than it is now furnished by telegraph companies, and with equal efficiency, the argument might be a strong one in favor of the adoption of the proposition. But I am not satisfied from any evidence that if these properties were taken over by the Government they could be managed any more economically or any more efficiently, or that this would enable the Government to furnish service at any smaller rate than the public is now required to pay by private companies."

Military Telegraph Pension Bills.

There are two military telegraph pension measures before Congress, i. e., House Bill 2920, introduced by Congressman Edward L. Taylor, Jr., of Ohio, and referred to the Committee on Invalid Pensions of which Representative Isaac R. Sherwood, of Ohio, is chairman, and Senate Bill 4625, introduced by Senator John W. Kern, of Indiana, and referred to the Committee on Pensions of which Senator Porter A. McCumber of North Dakota is chairman. These bills are in effect the same, providing as they do that "any person who served ninety days as a military telegraph operator during the Civil War . . . shall be held and considered to have been mustered into the military service of the United States at the date of employment in said Military Telegraph Corps, and to have been honorably discharged therefrom at the date said employment ceased, *Provided*, That no pension shall accrue prior to the passage of this Act."

The campaign to secure pensions for the military operators who served in the Civil War has been conducted with great vigor. From the different sections of the country the members of the corps have been active in soliciting the support of members of Congress and United States Senators for the bills now before Congress and the response has been very gratifying. Colonel W. B. Wilson, president of the society, spent a week in Washington recently and reports that the sentiment in both Houses was most favorable to action during the present Congress. He says, however, that until the big pension bill (Dollar-a-Day Bill) is out of the way the military telegraphers will have to wait. When that measure is disposed of he was assured by those in positions of authority that action would be taken on the telegraph bill.

Mr. A. A. Zion, of Indianapolis, Ind., is the chairman of the congressional committee of the Society of the United States Military Telegraph Corps, and is doing vigorous work to secure favorable congressional action on the pension bill.

The Turner Monument Fund.

Substantial contributions toward the fund to defray the cost of the monument to be erected at Harriman (Turner), N. Y., to commemorate the sending of the first telegraphic train order, continue to come in. In our issue for February 16 we announced the receipt of $500 from Mr. Andrew Carnegie, and many railway officials are now aiding the project. Mr. W. H. Truesdale, president of the Delaware, Lackawanna & Western Railroad, New York, in a letter enclosing his check for $10 toward the Fund, says, regarding the monument, "It is a most fitting memorial to erect and I am very glad to contribute towards it."

The bronze tablet of the Turner monument is again on exhibition in the window of the Gorham Manufacturing Company's store at the corner of Fifth Avenue and Thirty-Sixth Street, New York. All those who are interested in the monument project and especially those of a high artistic sense should see this beautiful bronze casting. A replica of the tablet is shown in the studio of Charles Keck, the sculptor of the tablet, at 148 West Thirty-sixth Street, New York. The tablet was illustrated in our issue for October 1, 1911.

Mr. David Homer Bates, of New York, member of the Fund Committee, is entitled to much credit for his active interest in behalf of the movement and his work is showing substantial results.

The fund now stands as follows: Previously acknowledged, $2,290.09; W. H. Truesdale, New York, $10.00; D. Colestock, Titusville, Pa., $5.00; Frank N. Dowler, Brooklyn, N. Y., $5.00; Ralph H. Wallace, New York, $5.00; W. H. Woolverton, New York, $5.00. Total, $2,320.09.

Telegraph in Austria.—The Austrian Post and Telegraph Department will make considerable extensions to the telegraph and telephone service during the year. Eleven million kronen ($453,600) have been appropriated for the purpose.

Ocean Wireless Letter-Telegram.

Ocean travellers often wish to send lengthy communications quickly on various business and social subjects, but do not care to go to the expense of sending their message by wireless telegraphy or cable. To meet this demand, the Deutsche Betriebs-Gesellschaft für drahtlose Telegraphie has introduced a form of ocean letter-telegrams.

The message is sent from the steamer by wireless telegraphy to a steamer going in the opposite direction, the operator mailing it on his steamer's arrival at its destination. On the transatlantic trip a letter will, in this way, arrive about seven days before it otherwise would, and on the trip between Lisbon, Portugal, and Rio de Janeiro, Brazil, about fourteen days are gained.

The charge for this ocean letter is $1.25 for thirty words, and 2½ cents for each word in addition. Not over one hundred words can be sent in this way, unless the service is not otherwise in use. Twelve and one-half cents are charged for postage.

This development of the ocean wireless letter-telegram is only in operation on the German steamship lines, on which boats the Telefunken system of wireless telegraph is used.

The Railroad.

Mr. A. L. Edgecomb, superintendent of telegraph, Bangor & Aroostook Railway, Bangor, Me., has gone South for his health. In passing through New York, he called on friends.

Mr. W. S. Tinsman, recently appointed assistant to the president of the Rock Island Lines, at Chicago, was formerly a railroad telegrapher, and has filled many important railroad positions.

New York Visitors.—Several railway telegraph superintendents visited New York recently, viz:—Mr. Charles Selden, general inspector of transportation and superintendent of telegraph, and E. W. Day, assistant superintendent, Baltimore & Ohio Railroad, Baltimore, Md.; W. P. Cline, Atlantic Coast Line, Wilmington, N. C.; S. A. D. Forristall, Boston & Maine, Boston, Mass.; G. A. Cellar, Pennsylvania lines, west of Pittsburg, Pittsburg, Pa., and N. E. Smith, New York, New Haven & Hartford Railroad, New Haven, Conn.

Railway Telegraph Superintendents.

A joint meeting of the Eastern and Western divisions of the Association of Railway Telegraph Superintendents will be held in the assembly room of the Chicago & Northwestern Railway, Chicago, Ill., at 10 a. m., March 20. It has not been fully decided as to what matters will be discussed at that time, but inasmuch as the annual meeting is to be held in New York in June, the date of which may be changed to the first week in that month owing to the national conventions to be held later it was thought best to hold another joint meeting in the West, at which time concerted action could be taken as to the plans for the annual convention. The New York convention will be held at the Waldorf-Astoria which will be the headquarters, and a banquet will probably take place at this hotel.

During the week beginning March 18, the Maintenance of Way Association will meet in Chicago and on March 19 the Signal Engineers will also meet in that city. Several railway telegraph superintendents are members of the latter body. There will also be an exhibit of apparatus and devices of interest to the superintendents held in the Coliseum building and a number of the members may avail themselves of the opportunity to attend.

The Committee on Miscellaneous Matters of the Association of Railway Telegraph Superintendents has issued blank forms to the members for the purpose of gathering information on, 1, Methods for protection of linemen and others handling wires; 2, Protection of telegraph poles against grass fires; 3, Practice as to charge for raising wires to permit house-movers and others to pass under; 4, Key for use in handling code and other messages by telephone. The committee consists of E. A. Chenery, Missouri Pacific Railway, St. Louis, Mo.; Geo. Boyce, Chicago, St. Paul, Minneapolis & Omaha, St. Paul, Minn.: L. M. Jones, Atchison, Topeka & Santa Fe, Topeka, Kan.; E. C. Keenan, Lake Shore & Michigan Southern, Cleveland, Ohio; V. T. Kissinger, Chicago, Burlington & Quincy, Chicago, Ill.; J. B. Sheldon, Union Pacific, Omaha, Neb., and F. T. Wilbur, Illinois Central, Chicago, Ill.

Further information may be obtained from Mr. P. W. Drew, superintendent of telegraph Milwaukee, St. Paul & Sault Ste. Marie Railway, Chicago, Ill., who is secretary of the association.

Telephone Train Dispatching in 1911.

(Continued from page 124, February 16.)

Mr. C. W. L. Mickley, superintendent of telegraph, International & Great Northern Railway Company, Houston Tex.: "We have no train dispatching or long distance telephone circuits in operation on this road and none are contemplated. We installed a duplex circuit between Houston and Palestine, a distance of 150 miles, on January 1, which is giving entire satisfaction."

Mr. F. T. Wilbur, superintendent of telegraph, Illinois Central Railroad Company, Chicago: "We are gradually increasing our telephone facilities, and wherever a new circuit is established there is so much use found for it that we wonder how we have been getting along without it. Like a number of other railroads, we have gone into the long line phantom arrangement to some extent and find that we can increase our facilities considerably at a nominal expense by adapting our circuits to phantom uses."

Digitized by Google

Mr. F. H. Van Etten, Superintendent of Telegraph, Chicago, Terre Haute & Southeastern Railway Company, Chicago, Ill.: "We have only one division equipped with a telephone train dispatching circuit. This circuit is 155 miles long, and with its use we have been able to handle our trains this winter, with one set of dispatchers, whereas with the Morse circuit, it required two sets. There is no question as to its preference over the Morse for this purpose. We are also using this telephone circuit for a simplex Morse circuit, and also for one side of a metallic composite telephone circuit which practically gives us three different services on this pair of wires. The telephone dispatching circuit was installed September 1, last year."

Mr. W. L. Connelly, superintendent telegraph, Chicago, Indiana & Southern Railroad Company, Gibson, Ind.: "During 1911 we installed one local telephone message circuit which completed the elimination of the telegraph for train dispatching and local message work, the other dispatching and other telephone message lines having been installed prior to 1911. This work is handled in a very satisfactory manner by telephone. At the present time our telephone dispatching and local message lines are utilized for simplex circuits; we expect to phantom these lines for through telephone circuits. We are on a strictly telephone basis and find the arrangement more satisfactory than we even hoped for, and very much better in every way than the telegraph. The Indiana Harbor Belt Railroad Company also installed one telephone line during 1911 to replace the local telegraph. We now do all train dispatching and message work by telephone on this road, having eliminated the telegraph entirely. The other dispatching and other telephone message lines were installed prior to 1911."

Telegraphers of Today.

An excellent opportunity is offered to telegraph people in general to become acquainted with over 600 prominent telegraph officials and others identified with the telegraph, the railroad, the submarine cable and press associations of the past generation, through their portraits and sketches of their careers as published in "Telegraphers of Today."

This work was issued in 1894 and includes biographical sketches of all the individuals connected with the interests mentioned at that period, many of whom have passed away from their earthly labors. The younger generation, however, will find much of interest in looking upon their portraits and reading of their achievements in life. Many of them are still alive and in harness in the telegraph and other fields of activity.

Mr. J. J. Ghegan, president of J. H. Bunnell & Co., New York, who recently received a copy expresses his appreciation of the work as follows: "Copy of 'Telegraphers of Today' received. I casually saw a copy of the book when first published, but never had I an idea that it was so beautiful, interesting and historically accurate. It should be of great interest to telegraphers with any sentiment in their makeup. It is magnificent, unique and I truly pity those of the fraternity who fail to secure a copy before the edition is exhausted."

This book, which is 11½ x 14 inches in size, was originally published at $5 per copy, but in order to close out the remaining copies we offer them at $1 per copy by express, charges collect.

Send orders to TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Delegates to National Civic Federation.—Among the delegates designated by Governor Dix of New York to represent the State at the annual meeting of the National Civic Federation, to be held in Washington, D. C., March 5, 6 and 7, are Messrs. Andrew Carnegie, Theo. N. Vail, president of the Western Union and American Telephone & Telegraph Companies, New York, and W. C. Brown, president of the New York Central Lines, New York.

Independent Railroad Telegraph Lines.—The Georgia Railroad Telegraph Company, with a capital stock of $200,000, has filed articles of incorporation. It is organized by officials of the Georgia Railroad for the purpose of building telegraph lines for its own use along its right of way. The headquarters will be at Augusta, Ga.

Trade with Porto Rico.—Shipments of telegraph, telephone and scientific instruments to Porto Rico from the United States during 1911 amounted to $223,713. Trade between the United States and that island for the year amounted to $72,000,000 which is eighteen times as great as it was in 1897, the year preceding the annexation of the island by the United States.

Franchise Taxes in Portland, Ore.—The county court at Portland, Ore., recently ordered the sheriff to seize the tangible property of the Western Union Telegraph Company, the Postal Telegraph Cable Company and the Pacific States Telephone & Telegraph Company because they have refused to pay the franchise tax levied against them. The companies contend that the franchise tax is illegal.

Report of Commissioner of Patents.—The report of Mr. Edward B. Moore, Commissioner of Patents, for the year ending December 31, 1911, shows that 33,927 patents were issued, and 19,875 patents expired.

Mr. J. W. McMahon, district commercial manager of the Western Union Telegraph Company, New York, in renewing his subscription for another year, writes: "I take pleasure in renewing my subscription to TELEGRAPH AND TELEPHONE AGE, which I consider the best medium, if not the only one for the telegraph fraternity, to keep in touch with the practical and progressive side of the profession, not to mention the social and personal notes which make interesting reading."

THE MOST SUCCESSFUL ELEMENTARY WORK.

A B C OF ELECTRICITY

By WM. H. MEADOWCROFT

One volume, 12mo. cloth, 50 cents. Fully illustrated.

This excellent primary book has taken the first place in elementary scientific works. It has received the endorsement of Thos. A. Edison. It is for every person desiring a knowledge of electricity, and is written in simple style, so that a child can understand the work. It is what its title implies, the first flight of steps in electricity.

Recent Experiments in "Wired Wireless" Telegraphy.

Some interesting additional data have been obtained from the office of the Signal Corps, War Department, on experiments in continuation of those that were made on January 21 with the "wired wireless" system invented by Major George O. Squier, U. S. A., says *The Electrical World*. Through the courtesy of Mr. M. M. Davis, chief engineer of the Postal Telegraph-Cable Company, New York, tests were made by Major Squier on Sunday, February 11, on a line extending from the Signal Corps laboratory at the Bureau of Standards in Washington, to 253 Broadway, New York. Both a metallic circuit and a grounded circuit were used in the tests, the line being a mixed commercial line consisting of No. 9 B. & S. copper wire on poles, subterranean cable line in Baltimore, and subterranean and submarine cable lines through Philadelphia and entering New York. The total resistance of metallic circuit was about 3200 ohms. No change whatever was made in this circuit as used in regular commercial telegraph service.

The principal object of the experiments was to determine important data as to the range of frequencies to be employed in reaching the longer distances by the "wired wireless" system and also the order of magnitude of the energy necessary and sufficient for such purposes. The measurements taken at the transmitting end of this line extended over a range from 34,000 cycles per second down to about 22,000 cycles.

The prime importance of tuning such a line to resonance and the comparative case with which this can be done with the commercial wireless apparatus were clearly demonstrated. This tuning of the line, whether a metallic circuit or a grounded circuit, required only a few minutes.

A number of experiments were conducted to determine the most suitable form of coupling between the generator circuit and the line circuit, the generator being directly connected to the line through the tuning elements as well as by the more usual manner of inductive connection. It was found that inductive coupling to the local generator circuit is far more efficient and convenient and, further, enables a number of lines to be operated from one generator with great ease.

At the receiving end the ordinary wireless-telegraph receiving equipment was employed, using the "audion" detector with high-resistance telephone receivers, and the elements were tuned to the particular frequency being transmitted. It was found desirable to tune the line both at the transmitting and at the receiving end and to adjust the coupling to the optimum value in both cases.

The importance of operating these circuits at resonance was strikingly observed since, when the generator terminals were directly connected to the line without the tuning elements, only the smallest readable current was obtained, whereas with proper tuning this current could be multiplied some hundredfold. With a transmitting current of 260 milliamperes at 22,000 cycles per second, signals just audible were heard in New York, thus indicating the lower limit of transmitting power with the particular line and frequency in use.

In the previous experiment with a line to Baltimore, about forty-eight miles long, frequencies up to 44,000 were used with a transmitting current of only 180 milliamperes, giving very loud and clear signals far above what would be necessary in traffic.

A large number of physical measurements were made on February 11 at the transmitting end of the New York line over a comparatively wide range of frequencies, and the results obtained conform to what was expected from previous work on other lines. It appears evident to War Department experts that the range of frequencies for "wired wireless" will extend from about 10,000 per second, as a lower limit, up to about 100,000, which is considerably above the lowest frequency now employed in long-distance radio-communication.

Just as in pure radio-telegraphic work the longer wave-lengths are used for the greater distances, so in "wired wireless" the longer wave-lengths corresponding to the lower frequencies will be employed, it is believed, for the long-distance circuits, reserving the shorter wave-lengths and lower power for the shorter circuits; thus the range from 10,000 to 25,000 cycles per second will be used on the long circuits and the upper region between 25,000 and 100,000 cycles will be used on the shorter circuits.

The proposed high-powered navy station in Washington, which will be in operation next July, uses a power of 100 kw and has a range of 3000 miles with a wave-length of 4000 meters which corresponds to 75,000 cycles per second.

It is clear from the above figures that the great increase in efficiency obtained by directing electric waves along wires to their destination, as shown by the amount of power required to send audible signals over such a circuit as already described, is beyond question. The plant necessary to transmit messages from Washington to New York by pure radio-communication would be of about 5-kw rating. In addition to the advantage obtained by directing waves to their destination, perhaps the greatest advantage is the fundamental one of freedom from interference between messages, which is ever present in wireless communication. The wire system guides the waves to their destination with greater efficiency and practically confines the electromagnetic disturbances between the conductors and prevents the waves from spreading outward in every direction in space, as is the case in radio-communication.

In the opinion of experts in Washington pure radio-telegraphy, which is now an infant art, scarcely more than twelve years old, has no competitor in the marine field, that is, between ship and ship and between ship and shore. On the other hand, on land, especially in congested dis-

Digitized by Google

tricts, even if the process of selective tuning should be developed so as to select messages by pure radio methods, radio-communication would still be totally inadequate, in the absence of wires, to handle the traffic of a large city.

The so-called "wired wireless" fills in the gap between the pure radio art and the wire art and indicates lines of development wherein one can apply the principles of wireless engineering to wire circuits and create additional telegraphic and telephonic channels for commercial use without the extra cost of maintenance over the use of such circuits for other electrical purposes.

The English Operator Under Government Operation of the Telegraph.

On page 108 of our issue for February 16 we printed an account of the existing dissatisfaction among telegraphers in South Australia. They have been agitating for better conditions for the past ten years, but the persistency of officials in decrying the work of the telegraphers is the chief obstacle they have to contend with.

A letter from Mr. H. Parker, parliamentary secretary of the Postal Telegraph Clerk's Association of England, on the condition of telegraphers under government ownership of telegraphs in that country, is not very enthusiastic on the subject.

"The rank and file of to-day," says Mr. Parker, "get more money than the rank and file of 1870 or 1880, but our chances of promotion to a superintendent's rank are very much smaller. You can take it that the ordinary man cannot expect more than the maximum pay of his class."

But the conditions are different between America and England, as Mr. Parker goes on to show, in that only in the large towns do telegraph operators work entirely at the wires. In other places they are employed on all other classes of postal work. Still the Englishmen believe they are better off than under a company.

Describing the conditions of employment in England, Mr. Parker says:

"The employes in the cable companies receive slightly higher wages than we do while the telegraphers of the railway companies of this country receive 25 to 40 per cent. less in any town. The employes of the cable companies are few in number, and I doubt if their pension prospects are as good as our own.

"There are two classes of telegraphers," he continues, "established and unestablished. The latter are very much underpaid, but they are employed generally in shops where general post office business is carried on or at times of pressure in seaside resorts, etc. They have small pay and no certainty of continuous employment. We are continually fighting to improve their conditions, with the view of preventing their blacklegging us.

"The situation is somewhat different in England to America, inasmuch as only in the large towns are telegraphers employed solely on such work. In the smaller towns the post office clerk is employed on telegraphy as well as all other classes of postal work.

"I am dealing now solely with established employes, who have continuity of employment, holidays, sick pay, and pensions, the latter being based on one-eightieth of his retiring salary for every year's service, together with one year's salary, which latter is paid to his survivors if he dies while still in employment. If he retires at any time he receives this sum or a proportion thereof.

"In London the telegrapher receives 65 shillings ($15.60) per week, and in other towns, of which there are five classes, the maximum wage ranges from 56 shillings ($13.45) to 40 shillings ($9.60) per week.

"There is very little moving about in England. A man is likely to stop in one town all his life if he so wishes. The only movement is where he desires to shift to a town with a higher maximum.

"The ordinary holiday is twenty-one days, exclusive of Sundays, after five years' established service. A man has to serve two or three years before becoming established. Full sick pay is given for six months and half pay for the next six months, unless the officer is pensioned during that time.

"Whatever our complaints—and they are many—we are infinitely better off than telegraphers in railway employment, who are the only other body of telegraphers in this country.

"We have a good organization and have been very successful, but we suffer one drawback, and that is that all our officers are still in Government employment, and consequently we have not sufficient time at our disposal to do the work we should like."

The Reid Monument.

At the meeting of the Reid monument committee, at 253 Broadway, New York, on February 14, Mr. Charles P. Bruch was elected chairman and W. B. Dunn, secretary. Col. A. B. Chandler was elected treasurer of the fund. Twelve members were present and an executive committee of five was appointed to carry on the work, which is to secure funds for the erection of a suitable monument or a memorial to commemorate the telegraphic career of the late James D. Reid, whose remains are buried in Mount Hope Cemetery, Rochester, N. Y.

The executive committee consists of the chairman, secretary and treasurer of the general committee (ex-officio), David Homer Bates, L. B. Foley, J. R. Beard, R. J. Marrin and W. J. Dealy.

Extending the Telegraph in South Africa.—Two new telegraph lines are to be run from Capetown to Johannesburg, South Africa, and a third from Capetown to Durban, while others are contemplated.

Digitized by Google

Typewriters in Telegraph Service.

Few things have happened in many years of more interest to telegraphers than the recent purchase by the Western Union Telegraph Company of 10,000 Underwood typewriters.

It means the adoption officially by this great service of one machine to be used universally throughout the country in its many thousands of offices. Prior to today the typewriter question from a company's standpoint has never been taken up by any telegraph company. Operators were encouraged to buy machines, with the result that they purchased makes of every nature. The average telegraph office oftentimes took on the appearance of a second-hand typewriter exchange. One operator would be using the best character of machine, while another would be using a machine of less responsible manufacture.

The great increase in the business of the Western Union Company due to the popularity of the day- and night-letter service is partly responsible for the new innovation which will put the Underwood typewriter in every Western Union office.

The telegraph company believed that the efficiency of the service could be greatly increased by the use of writing machines and would make the telegraphic result positively legible.

The proposition of purchasing the machines was referred to a committee some months ago. This committee took into consideration, not only the necessity for the purchase of typewriters, but the practical and mechanical merits of all machines. The result was a report to the company in favor of the purchase and the adoption of the machine just ordered. Within a year every telegram, and particularly the day and night lettergram received over the Western Union wires, will be typewritten. When the method is fully in force, it is expected that a vast improvement in the character of the telegraph service will be apparent.

Western Electric January Sales.—January sales of the Western Electric Company were about 9 per cent behind those of January of last year, sales being goods billed out, but new business for the month was $500,000 in excess of the goods billed. January's total is at the rate of about $67,000,000 for the year, or approximately the same as 1911, whose total was $66,300,000. Foreign business shared in the decrease but not to the extent of domestic business. Extent of operations and gross business of the company has grown steadily, but the trend of the margins of profit has been smaller in the last few years. The cost of skilled and unskilled labor has increased, as has also the price of raw materials, but the price of manufactured goods has shown almost no advances. Against the proportionately greater increase in cost of operations, the company has set scientific management and the development of its sales organization and in both branches it has attained a high degree of efficiency.

Roebling Catalogue.—The John A. Roebling's Sons Company, Trenton, N. J., has just issued a handsomely gotten-up catalogue of its wire rope and wire products. It opens with a history of the business founded by J. A. Roebling in 1840, and gives a description of the enterprise as it is today. Many pages of the catalogue are devoted to telegraph and telephone wire, and wires of special shapes, and the many products of the well-known concern are very completely catalogued and illustrated. The illustrations deserve special mention for their high artistic merit and many interesting views of bridges, warships, etc., on which Roebling wires and cables are used are shown.

The catalogue bears evidence of careful preparation, and contains useful tables for telegraph and telephone engineers. Any one interested in the use of wire rope and wire can obtain a copy of this catalogue on application to the company's office at Trenton, N. J.

LETTERS FROM OUR AGENTS.

PHILADELPHIA WESTERN UNION.

Mr. Mahlon G. Moyer, traffic manager, has gone on a three months' vacation to the Holy Land. He will visit Switzerland, London, Paris and Berlin.

Mr. Frank Webb, general traffic manager, celebrated his fifty-fourth birthday on February 16 and was the recipient of many presents from the operating force.

Mr. I. D. Maize celebrated his seventieth birthday on February 28.

The Telegraphers' Mutual Benefit Association, 105 Broadway, New York, combines fraternalism with sound business principles; it offers to the telegraph and telephone employe an absolutely safe form of protection, at a cost within the reach of all and lower than can be found elsewhere. Membership is only open to employes in commercial or railroad telegraph or telephone service, and it is manifestly to the interest of those who are eligible and wish to secure life insurance within their means, to secure without delay a certificate for $1,000 or $500, or both, at rates based on present age.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

How We Progress. Opportunities Always Waiting.

One of the greatest mistakes the present generation makes is its tendency to believe that the opportunities offered today for advancement in the way of new inventions and the further development of existing means, are very slight compared with the opportunities offered in earlier days.

In plainer words, the idea seems to prevail that the field has practically been about covered and the best fruit nearly all gathered.

Now a little thought concerning the manner in which we progress will show that the period of time has nothing whatever to do with it. The fact is, today, or a hundred years hence, invariably offers the late-comer, with his better facilities and enlightenment, as great, if not greater, opportunities than were ever offered his predecessors. This fact should be obvious to any one who will remember that every "today" stands at the head of "yesterday" and consequently he sees farther ahead. "Today," also, not only possesses all the knowledge and experience of "yesterday" without having to first dig it out, but begins where the latter left off. The field undoubtedly still contains more and better fruit than man will ever be able to gather, so there is positively no excuse for any one to become discouraged.

The layman asks, "Well, what shall I invent? Everything I can think of has already been covered." That is not the way to approach the matter. His thoughts should be something like this: "What is needed, or wanted? or how can I improve the weak spots in some present device?" There is not a person living, possessing average intelligence, that could not name hundreds of things that would be valuable if evolved, or who does not see defects in nearly all industrial devices, the elimination of which would enhance their value greatly. Because a defect of long standing still exists, does not argue that the fault may not eventually be remedied. This is the field the layman should first explore, for it is in this direction that one is most likely to uncover a new quarry. In fact, nearly all our most valuable inventions were stumbled upon accidentally while in pursuit of other objects.

But let us be specific. For example, take the telegraph and telephone and look over the field.

Professor Morse discovered the fundamental principle involved in telegraphy, and invented a device for its practical operation. It was certainly a great discovery and met the wants of that particular "today," yet his invention would not meet the demands of the present "today;" nor would the professor be able to even relieve one of our quadruplex men for lunch were it possible for him to drop in on us again. His knowledge of electricity would be very meagre, indeed, compared with even that of a novice of today, yet had he, or some one else, not made the first step, there would have been no head or shoulder for followers to stand on, and thus see farther ahead.

It was many years after Morse's invention before the duplex and quadruplex were invented, and many more before the dynamo method of generating electricity was evolved, yet the officials of the companies and others knew what was required long before the means arrived.

Chemical batteries were expensive, cumbersome and unavailable for "divided" circuits where great volumes of current were required, but the dynamo solved the problem.

When the dynamo was installed, it was naturally concluded that nothing more could be desired, but it was soon discovered that it was unavailable for long quadruplex circuits requiring high potentials with the style of polechanger then used. How to get a "long" and a "short-end" current from the initial pair of dynamos was another problem to be solved, yet the man on deck at that period saw the weak spot and remedied it. That gentleman's name is Mr. Stephen D. Field, at one time the electrical engineer of the Western Union Telegraph Company. Mr. Field, who installed the dynamo system at 195 Broadway, New York, in 1879, and

Digitized by Google

threw out approximately 100,000 cells of gravity battery, told the writer a very interesting story in connection with the old standard Field-key and walking-beam polechanger system of which he was the inventor.

Mr. Field said, as near as the writer can remember, that but little thought was taken of ways and means for surmounting this difficulty at first, as it had been decided to install a method devised and patented by Mr. F. W. Jones, who was afterward electrical engineer of the Postal Telegraph-Cable Company, New York. Mr. Jones' method was to use four dynamos, two positives, and two negatives, or two pairs of machines connected in series, as shown theoretically in the accompanying diagram.

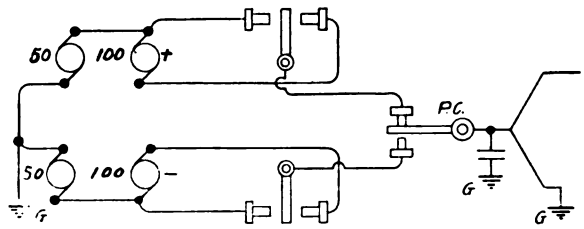

DIAGRAM SHOWING THE THEORY OF THE JONES QUADRUPLEX.

The "short" end was obtained by tapping between the two machines in series.

A few days before the installation was finished, Mr. Field concluded that there certainly was some way by which one machine might be made to furnish both currents and determined to solve the problem then and there. He tells us that for two or three days and nights the problem never left his mind. About four o'clock one morning, he woke from a troubled dream with the "leak" idea in his head, and the very next day set up an experimental quadruplex with resistance coil values obtained by experiment, and soon had the satisfaction of seeing the system in actual operation.

Later, Mr. George A. Hamilton, then electrical engineer of the Western Union Company, worked out the mathematical problem for the resistance coils and developed the formula since used.

This story is repeated here merely to show that there is not only always present needs, but that there is probably a remedy for all defects if one will but persist in the search until it is found.

For example, one of our greatest needs today, is a satisfactory remedy for the harmful effects of "induction." So far, no one has been able to find it, because it is an inconstant quantity, while our magnets are operated by practically constant values of electrical energy. But it is possible that some day some one may utilize this enemy usefully and compel him to lift himself by his own boot straps or keep quiet.

Recent Telegraph and Telephone Patents.

ISSUED FEBRUARY 13.

1,017,054. Telegraph Sending Machine. To J. A. Hulit, Topeka, Kan.

1,017,064. Galvanic Battery. To E. C. Smith and E. L. Marshall, Cleveland, Ohio.

1,017,080. Storage Battery. To J. P. Clare, Stratham, N. H.

1,017,085. Telephone System. To F. M. Davis, Chicago, Ill.

1,017,169. Method of and Apparatus for Transmitting Signals over Telegraphic Circuits. To L. M. Potts, Baltimore, Md.

1,017,362. Sanitary Protector for Telephone Transmitters. To C. Adams, New York.

1,017,398. Telegraph Key. To J. E. Folsom, St. Louis, Mo.

1,017,616. Telephone Repeating Apparatus and Circuits. To C. Adams-Randall, Augusta, Me.

1,017,617. Apparatus for Increasing the Efficiency of Telephone Lines. To C. Adams-Randall, Augusta, Me.

ISSUED FEBRUARY 20.

1,017,680. Sanitary Mouthpiece for Telephones. To M. M. Marcuse, New York.

1,017,967. Telephone Selecting Device. To F. E. Granger, Aberdeen, S. D.

1,018,082. Telephone Transmitter. To C. R. Rogers, Waverly, N. Y.

1,018,115. Telegraphic System and Apparatus. To C. Kinsley, Chicago, Ill.

1,018,182. Telephone Transmitter. To F. Gottschalk, New York.

1,018,226. Telephone Repeating System and Apparatus. To C. Adams-Randall, Augusta, Me.

1,018,375 and 1,018,376. Signaling System. To H. O. Rugh, Sandwich, Ill.

ISSUED FEBRUARY 27.

1,018,646. Automatic Telephone Instrument. To J. Weil, Mansfield, Ohio.

1,018,666. Telephone System. To H. F. Joeckel, Camp Point, Ill.

1,018,730. Mouthpiece for Telephone Transmitter. To C. M. Swingle and A. M. Miltenberg, Chicago, Ill.

1,018,940. Electrical Communicating Apparatus. To T. M. St. John, New York.

Telegraph and Telephone Stock Quotations.

Following are the closing quotations of telegraph and telephone stocks on the New York Stock Exchange March 11:

Amer. Telep. and Teleg. Co.	146
Mackay Companies	81
" " pfd.	69
Western Union Tel. Co.	84½

Telegraph Statistics of British Colonies.—The telegraph mileage in the British colonies in 1910 as shown by recent statistics was as follows: British India, 72,746; Australia, 43,492; Canada, 36,517; New Zealand, 11,316; Cape Colony 8,466; Rhodesia, 4,404; Nigeria, 6,489.

Mr. J. F. Sheldrake of Philadelphia, Pa., writes: "The receipt of TELEGRAPH AND TELEPHONE AGE is always awaited with eagerness, and, in addition to the valuable knowledge derived from its educational articles, it affords me untold relaxation from the daily routine in its social and personal columns."

Digitized by Google

Personal.

Mr. Thomas A. Edison has gone to Fort Myer, Fla., to spend a few weeks.

Lena J. Brant, wife of the late John Brant, secretary of the Old-Time Telegraphers and Historical Association, has gone on a trip to the Holy Land.

Mr. A. W. Orton, an old-time telegrapher and a member of the United States military telegraph corps, is now a prominent business man of Rome, N. Y. He is president of the Rome Box and Lumber Company, which is one of the leading industries of that city.

Mr. Melville E. Stone, general manager of the Associated Press, New York, will address the Kansas State Editorial Association at its annual meeting in Leavenworth, Kan., in April.

Dr. Alexander Graham Bell, of Washington, D. C., has been awarded the Elliott Cresson gold medal by the Franklin Institute, Philadelphia, Pa. This medal is the highest gift in the Institute.

Col. R. C. Clowry, formerly president of the Western Union Telegraph Company, New York, accompanied by his secretary, Mr. Frank J. Scherrer, has returned from Jekyll Island, Ga., where he spent a few weeks.

Mr. Arthur Lockwood, who has been connected with the Western Electric Company for some time past, has accepted a position in the sales department of the Brookfield Glass Company, New York.

Mr. B. D. Snyder, second day wire chief of the Western Union Telegraph Company at Dallas, Tex., has resigned to engage in the real estate business in that city. He is succeeded by Mr. C. V. Depew of Omaha, Neb.

Major George O. Squier, of the Signal Corps, United States Army, has been appointed military attaché to the United States Embassy at London, and will leave for London in June. Meantime he will make a trip to the Isthmus of Panama to select sites for five wireless stations.

Mr. George M. Myers, an old-time telegrapher and a capitalist of Kansas City, Mo., is taking a trip around the world on the steamer "Cleveland" of the Hamburg-American Line. When last heard from he was in Honolulu on his way to Japan, where he is at the present time.

Mr. J. Frank Howell, a former telegrapher, and now a prominent stock broker, is a candidate for the presidency of the Consolidated Stock Exchange, New York. One of the conditions of his acceptance of the office, however, is that it be made a non-salaried position as on the New York Stock Exchange.

Mr. Franklin H. Reed has severed his editorial connection with *Telephony* of Chicago and joined the organization of The Traffic Service Bureau, of Chicago and Washington. His time will be largely devoted to the development of The Traffic Service Bureau's paper, *Public Service Regulation*, the official journal of the National Association of Railway Commissioners.

Mr. B. M. Downs, vice-president and a director of the Brookfield Glass Company, New York, has resigned, and will take a rest from business cares before entering upon new duties. Mr. Downs has been connected with the Brookfield Glass Company for over a quarter of a century, and has a host of friends in the electrical field, who will wish him much success in his future business relations.

Dr. A. E. Kennelly, professor of electrical engineering at Harvard University, Cambridge, Mass., and a former telegrapher, on March 1, gave an interesting talk on "Electrical Communication," before the Luncheon Club branch of the New England Section of the National Electric Light Association, Boston, Mass. He dwelt particularly upon ocean cable telegraphy, wireless telegraphy and telephony.

Major W. A. J. O'Meara, engineer-in-chief of the Postal Telegraphs, London, England, owing to ill-health has resigned, and has been appointed engineering special commissioner, charged with the duty of examining and reporting upon the European telegraph and telephone systems for the British government.

Mr. W. Slingo, assistant engineer-in-chief of the Postal Telegraphs, London, has been promoted to be engineer-in-chief, vice Major W. A. J. O'Meara, resigned. Mr. Slingo is a well-known electrical engineer, and is a co-author of a handbook on electrical engineering, published in England.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. Chas. C. Adams, vice-president, New York, was in Baltimore recently on business in connection with the coming national convention.

The series of conferences between the general superintendent and the superintendents of the eastern division of the Postal Telegraph-Cable Company, and the president, the vice-presidents and other officers of the company in New York, was held on Monday, Tuesday and Wednesday, March 4, 5 and 6. Mr. Mackay presided over the meetings. He was deeply interested and took an active part in the discussions, which were confined to subjects relating to efficiency of service and economy of operation.

The following-named gentlemen were present at the conference: Clarence H. Mackay, president, Edward J. Nally, vice-president and general manager, Charles C. Adams, vice-president, Charles P. Bruch, vice-president and assistant general manager, Welcome I. Capen, vice-president, Minor M. Davis, electrical engineer, F. F. Norton, traffic manager, J. F. Skirrow, associate electrical engineer, Charles Shirley, assistant traffic manager, Edward Reynolds, auditor, E. B. Pillsbury, general superintendent, Leona Lemon, division superintendent, E. Kimmey and C. F. Leonard, superintendents, New York; C. E. Bagley, superintendent, Philadelphia, Pa., Harvey D. Reynolds, superintendent, Buffalo, N. Y.; C. A. Richardson, superintend-

Digitized by Google

ent, Boston, Mass., and Henry Scrivens, superintendent, Pittsburg, Pa.

On Monday evening, Mr. Pillsbury gave a dinner at the Crescent Athletic Club, Brooklyn, to his superintendents, and on Wednesday evening, Mr. Mackay gave a dinner at the Hotel Lafayette, followed by a theatre party, to all who participated in the conferences.

A conference of the general superintendent and superintendents of the Southern Division will be held on March 26, 27 and 28. Papers will be read on "Efficiency of the Service," by Jesse Hargrave, division superintendent; "Receipts," by W. C. Daviet, district superintendent, and "Expenses," by G. W. Ribble, district superintendent, all of Atlanta, Ga.

A conference of the general superintendent and superintendents of the Western Division was held in the executive offices, New York, March 12, 13 and 14. Papers were read by Mr. G. E. Paine, superintendent, Chicago, Ill., on "Efficiency of the Service;" Mr. W. C. Black, superintendent, Denver, Col., on "Receipts," and by Mr. H. G. McGill, superintendent, Chicago, Ill., on "Expenses." Mr. Paine's paper was discussed by Mr. J. F. Looney, Chicago, Ill., Mr. Black's paper, by Mr. A. L. Lafferty, Chicago, Ill., and Mr. McGill's paper, by Mr. A. B. Richards, Kansas City, Mo. Those present were Messrs. E. W. Collins, general superintendent; S. H. Mudge, division superintendent; C. M. Baker, division general superintendent of plant, and H. C. Shaw, division electrical engineer, H. G. McGill, G. E. Paine, J. F. Looney, A. L. Lafferty, W. P. S. Hawk and C. A. Comstock, superintendents, Chicago, Ill.; A. B. Richards, superintendent, Kansas City, Mo., and W. C. Black, superintendent, Denver, Col. The superintendents of the Eastern Division and executive officers of the company were also present.

The Postal Telegraph-Cable Company in connection with the German Cable Company has arranged with the government telegraph administrations for telegraphic remittances of money to all points in Germany, Switzerland and Luxemburg, from the United States.

Construction work has begun on the new Broadway subway adjoining 253 Broadway, and it is probable that a station will be established in this building. The barber shop in the basement has been removed in order to make room for the subway.

Mr. Arthur W. Cowles, cashier of the Springfield, Mass., office of this company, was married to Miss Clara Pauline Schortmann of the same place, on February 29.

Mr. E. W. Miller, chief operator at Philadelphia, Pa., was a recent executive office visitor.

The Mackay Telegraph & Cable Company is building its lines in the direction of Alexandria, La., and expects to open an office in that place soon.

Mackay Telegraph Lines in Texas.—The Mackay Telegraph & Cable Company will build a telegraph line along the right-of-way of the Texas & Pacific Railroad from Texarkana to Sherman, Tex., and from Texarkana to Shreveport and Alexandria, La., and along the 'Frisco line from Sherman to Dallas.

Atlanta Postal Club Election.—At the election of officers of the Postal Telegraph Club of Atlanta, Ga., on February 27, Mr. W. C. Daviet was re-elected president. The other officers elected were, A. M. Beatty, vice-president; L. A. Minor, secretary; F. F. Pursley, assistant secretary; G. W. Oliver, treasurer; G. W. Ribble and D. C. Delaney, governing committee. The annual banquet will be held on March 23, and it is expected that prominent telegraph men from different sections of the country will be present.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr. Belvidere Brooks, general manager, accompanied by Mr. T. W. Carroll, assistant to the general manager, and Mr. W. C. Merly, Mr. Brooks' secretary, are on a trip through the South on company business. The trip will take them as far as Jacksonville and Tampa, and they expect to return to New York about March 16.

Mr. W. E. Athearn, engineer of equipment, New York, has returned to his office after a three-weeks' trip through the South, including Havana, Cuba. He was much impressed with the progressiveness in the Southern division, and found equipment and operating staffs at all points, up-to-date in all respects. He was accompanied by Mrs. Athearn.

Mr. William L. Jacoby has been elected vice-president of the American District Telegraph Company of New Jersey. His headquarters are in the Riker Building, corner of Broadway and Dey Street, New York.

Mr. L. D. Beall, formerly chief clerk to Mr. E. M. Mulford, division commercial superintendent, New York, has been transferred to the general manager's office, as assistant to Mr. John C. Willever. Mr. Wilson S. Fowler has been promoted to be acting chief clerk, vice Mr. Beall.

Conferences were held by Mr. A. C. Kaufman, commercial agent, New York, with the local officials in Philadelphia, Baltimore and Washington, during the last week in February.

Mr. E. S. Peterson has been appointed acting chief operator at Helena, Mont., vice L. P. Grover, promoted to be chief operator at Salt Lake City, Utah.

The managers of the eighth district, Western Division, held a conference in Minneapolis, Minn., February 27. Among those present, besides the managers, were W. J. Lloyd, division traffic superintendent, and M. T. Cook, division commercial superintendent, Chicago, Ill.; A. D. Bradley, district commercial superintendent, and L. F. Wise, manager, Minneapolis, Minn. The managers were from Minnesota, North Dakota, South Dakota, Northern Wisconsin and Northern Michigan.

Digitized by Google

Mr. W. J. Sullivan, night chief operator at Detroit, Mich., has been appointed chief operator vice Charles H. Addison resigned. Mr. E. C. McConnell, assistant wire chief, has succeeded Mr. Sullivan as night chief. Mr. Sullivan was, from 1895 to 1897, assistant day traffic and wire chief, and all-night chief from 1897 to 1905. In 1905, he became day traffic chief and served in that position until 1909, when he became night chief, which position he held until his promotion to be chief.

This company has prepared for distribution among its patrons a leaflet giving tables of tolls for day letters, night letters and day messages. The tables show at a glance the cost of messages of any number of words up to 200 at various rates.

Some quick work was done in establishing a new office at Easton, Pa., at the time of the destruction of the old office by fire, on March 5. The fire started next door to the telegraph office at 5 a. m., and when it was seen that the office would be destroyed, new quarters were opened in a vacant store across the street, and wires were working to New York, Philadelphia and Scranton, from the new office while the former office was still in flames. This feat was accomplished by the united efforts of district plant superintendent W. J. Higgins, of New York; D. Roth, superintendent of construction; T. J. Smith, district wire chief; W. H. Collins, district plant chief, and C. C. Lever, general wire chief, who were all on the ground early, directing the work of establishing the new quarters.

Western Union Cable Unification.

The eight trans-Atlantic cables of the Western Union, Anglo-American and Direct United States companies were consolidated on March 8 under one operating management and will be known hereafter as the Western Union Cable System. This is the result of the recent leasing of the Anglo and Direct companies by the Western Union.

Announcement was also made of the following appointments for the new system: J. H. Carson, London, general operating manager; T. W. Goulding, London, European commercial manager; J. C. Willever, New York, United States manager.

The European headquarters will be in the Anglo-American Building, New Broad Street, London; the American headquarters will be in the Western Union Building, 195 Broadway, New York. The present receiving offices or their equivalent of the three companies in the various large cities of the world will be maintained, but all operations will be conducted by the new unified management.

Poles in Richmond.—About six years ago the Richmond, Va., city council passed an ordinance for placing all electric wires underground, and attached a penalty for each day the provisions of the ordinance were not obeyed after a certain date. The Western Union Telegraph Company not complying because of certain unreasonable provisions in the ordinance litigation resulted and the federal court upheld the legality of the ordinance. The Western Union then appealed the case to the Supreme Court of the United States, which now has the matter before it.

The Western Union in Kentucky.—The County Court of Jefferson County, at Louisville, Ky., has decided that the Western Union Telegraph Company has the right, under the statutes of Kentucky, to condemn property along the Louisville & Nashville Railroad in that State, for the erection of a pole line.

The Cable.

The Commercial Cable Company announces the extension of the deferred cablegram service to Argentine Republic, Spain, Canary Islands, Spanish possessions in North Africa, Morocco (except Casa Blanca, Mogador and Rabat), Senegal, Upper Senegal, Niger, and Mauritania. The rules governing this service are the same as those already announced with reference to the same class of service with other countries.

French Cable to Porto Rico. — The French Cable Company has made application to the United States government for permission to make a landing on Porto Rico of a branch of its Hayti cable.

Alaska Cable Repaired. — The government cable to Alaska which was out of service for several days owing to a break has been repaired by the cable steamer *Burnside*. The damage was caused by submarine slides.

Pacific Cable Repaired. — The break in the Midway-Guam section of the Commercial Pacific Cable was repaired on March 9, thus restoring communication with China, Japan, the Philippine Islands and the Dutch East Indies.

Deferred Cable Service from South Africa.—The Union of South Africa now accepts plain-language cablegrams, deferred not over twenty-hours, at one-half the ordinary charge, for the United Kingdom, all British possessions (except Egypt and the Sudan), the United States, France, Germany, Portugal and the Portuguese colonies.

The Reid Monument.

The Reid monument committee is preparing a pamphlet relating to James D. Reid which will be ready for distribution soon. It will be in the nature of a memorial and will set forth the object for which the committee was organized. It will also contain a reprint of Mr. Reid's biography from the "Telegraphers of Today;" reprints of the accounts of Mr. Reid's death and funeral from TELEGRAPH AND TELEPHONE AGE, and a copy of a letter written by Mr. Reid in which he states that he originated the telegraphic signal "73."

The committee is rapidly getting things into shape so that it can go ahead with its work in raising funds for the proposed memorial.

Digitized by Google

The Telephone.

Mr. B. E. Sunny, president of the Chicago Telephone Company, Chicago, Ill., will address the Commonwealth Edison Company Section of the National Electric Light Association, Chicago, on March 19.

Mr. H. B. Thayer, president of the Western Electric Company and vice-president of the American Telephone & Telegraph Company, New York, returned from Europe on the steamer *Lusitania,* arriving on March 14.

Mr. Alfred E. Holcomb, tax attorney, American Telephone & Telegraph Company, New York, delivered an address entitled "One Assessment—One Levy," at the second State Tax Conference held at Buffalo, N. Y., January 9, 10 and 11. The address has been reprinted in pamphlet form.

New Channel Telephone Cable.—The French government recently laid a new submarine telephone cable across the English channel, between Abbot's Cliff, Dover, England, and Cape Grisnez, France. It has two metallic circuits and is of the continuously-loaded type.

Long Private Telephone Line.—One of the longest private telephone lines is being built by the Southern Sierras Power Company, from San Bernardino, Cal., to its power plants near Bishop, Cal., a distance of 240 miles. The line will be used for public as well as for private service.

Telephone Herald Suspended.—The New Jersey Telephone Herald which was organized at Newark, N. J., to furnish various forms of entertainment by telephone during specified hours of the day and night has suspended after an existence of four months. Lack of capital is the cause given.

Telephone Party.—Society has taken up the telephone as a means of entertainment. A "telephone party" was given by a society young lady in New York, March 9, a feature of which was conversation by telephone between the guests. Miniature telephones of silver were given as favors.

Telephone Protection of Hen Houses.—A Connecticut poultry raiser ran a telephone circuit between his hen house and his bed room. At daybreak one morning, he was awakened by the loud cackling of his hens, and, seizing his shot gun, he started for the scene of the commotion. He shot and killed the thief, which was a mink.

Telephone Rate Making. — Mr. Alonzo Burt, first vice-president and treasurer of the Wisconsin Telephone Company, Chicago, Ill., delivered an address on "Some of the Problems of Telephone Rate Making," before the Wisconsin State Telephone Association, at Madison, Wis., on February 15. It has been published in pamphlet form, and gives much valuable and timely information on this important subject.

Consolidation in Sioux City.—The consolidation of the Sioux City, Iowa, Telephone Company with the Bell interests, was consummated in that city recently, the consideration being $2,500,000. The local company operates an automatic system and the new management will let the public decide whether it desires the automatic or the manually-operated system. The local company has 15,000 subscribers.

Telephone Election. — Mr. H. J. Pettengill, president Southwestern Telegraph & Telephone Company, Dallas, Tex., has been elected president of the Missouri and Kansas Telephone Company, vice Mr. C. S. Gleed, who has been elected chairman of the Board of Directors of the Southwestern Telegraph & Telephone Company. Mr. E. D. Nims was elected vice-president and treasurer; Mr. E. S. Bloom, second vice-president, and J. K. Wass, auditor. Mr. Benjamin S. Reed was appointed general manager of the St. Louis Division to succeed Mr. F. R. Mott.

Telephone and Telegraph in the Kongo.—All telephone and telegraph lines of the Kongo are owned and operated by the Belgian Government. The wires as a rule extend along railroad lines or the Kongo River and are used for both telephone and telegraph service. The approximate total mileage of wire is 1,685, of which 685 is not yet equipped with telegraph instruments. The charges for telephone messages range from about forty to ninety cents, according to distance, for five minutes' conversation, and from forty cents to $1.10 for fifteen words sent by telegraph.

A Petition Over Two Hundred Feet Long.—The Public Service Commission, Second District, New York, received a petition 226 feet in length, signed by 4,160 persons, asking the Commission to use its influence to induce the New York Telephone Company to make reasonable terms for the retention of public telephones in drug stores. The New York Telephone Company recently put into effect a regulation allowing druggists only ten per cent. of the receipts from coin slot instruments instead of twenty per cent. and upward as formerly. The company has, however, modified its regulation in such a manner that the druggists will be able to get practically their former commission.

The Washington-Boston Underground Line.

The American Telephone & Telegraph Company has completed the duct work for its Washington-Boston underground line, and expects to have the cables all drawn in by next fall.

This line will be the longest of its kind in the world, and was undertaken to insure service between the two points and intermediate cities at all times.

The distance between the two cities is about 475 miles, and an interesting feature of the cable is that it is to be phantomed and so designed that the phantom circuits, as well as the side circuits, of which they are made up, can be loaded.

A full description of this line was published in our issue for June 16, 1911.

Digitized by Google

Rules for Use of Telephone on Northern Pacific Railway.

Following are the rules of the Northern Pacific Railway Company for the guidance of its employes in the use of the telephone in the transportation department:

Speak directly into the transmitter in a moderate tone.

Where jack boxes are used plug must be left disconnected from the jack except when in actual use.

To answer a call: Insert plug in proper jack, take down receiver and *speak name of the station.*

To call dispatcher: Insert plug in proper jack, take down receiver and listen; if line not in use, say "Dispatcher" and name of your station.

Except train orders, which will be made complete in the usual manner, all communications will be acknowledged by "All Right" or "O. K.," followed by name of person receiving them.

In transmitting and repeating train orders, the following method will be observed:

Numbers one to nine inclusive will be pronounced, and then spelled thus: 1, O-N-E; 5, F-I-V-E, etc.

In numbers above nine, except time in the body of train orders, the figures will be pronounced separately, and then the whole number pronounced, thus: 1-0, ten; 3-2-5, three twenty-five; 2-3-7-8, twenty three seventy eight: (the figure 0 will be pronounced as though spelled Oh).

Time in the body of train orders, except in schedule orders will be pronounced and then spelled thus: 1-0-3-5; T-E-N T-H-I-R-T-Y F-I-V-E: 6-1-5; S-I-X F-I-F-T-E-E-N.

In transmitting and repeating time in schedule orders the figures will be pronounced separately and then the whole number pronounced, thus: 1-0-3-5, ten thirty five, etc.

Names of stations in the body of orders, except when repeating schedule orders, will be pronounced and then spelled thus: Hawley, H-A-W-L-E-Y; Winlock, W-I-N-L-O-C-K; etc.

Example of order as transmitted and repeated:

Number 1 *O-N-E engine* 2-1-6-2 *twenty-one sixty-two waits at Missoula M-I-S-S-O-U-L-A until* 1-2 3-5 *T-W-E-L-V-E T-H-I-R-T-Y-F-I-V-E P. M. for Number* 6-0-2 *six hundred and two engine* 2-3-7-8 *twenty-three seventy-eight.*

Example of same as written:

No. 1 *eng* 2162 *waits at Missoula until* 12 35 *twelve thirty five p m for No.* 602 *eng* 2378.

Trains should be reported thus:

OS Bluffton Number 1 *by* 4-20; *OS Heron extra east* 2-7-2-8 *by* 6-1-0, *etc.*

Trains may be reported without first calling the dispatcher, but the dispatcher should acknowledge getting the report by saying "All Right" or "O. K."

When in doubt, spell names and numbers. Confusion of similar sounds can be overcome by spelling such letters as T. B and C, etc., thus: T-E-A; B-E-E; S-E-E; etc., when necessary. Repeat until certain of being understood correctly.

When circuit is interrupted or selector signal inoperative, operators will cut in frequently in an endeavor to keep in touch with the dispatcher.

Portable Train Set as a Time-Saver

The loss of time entailed by the inability of crews of stalled trains and of repair gangs to communicate with headquarters from places along the right-of-way led the Lehigh Valley Railroad to purchase, in all, over seven hundred Western Electric portable telephone sets during the past year. Each train unit is furnished with one of these sets, as is each bridge crew and each track repair gang, and the officials of the road state that the purchase of these sets is one of the most profitable investments the company has ever made. As an instance of the utility of this modern device, one of the track repair gangs was sent out on this road recently with its first portable set, to replace worn rails. The "Black Diamond" express was due, according to schedule, just about the time the track foreman was ready to replace several rails. Under the old order of things, the track foreman would have waited until the express had passed before beginning work. He communicated by means of his portable set with headquarters and learned that the "Black Diamond" was two hours late. Knowing this, he went ahead with his work, made the rail replacement and had ample time to move on to the next place of operation before the train passed.

Among other uses, it may be mentioned that the bridge inspector can report minor troubles to headquarters and have a repair gang start toward the scene of action in less time than he could formerly reach a signal tower. In an emergency, such as a wreck, the train crew can communicate immediately with the dispatcher and give detailed information concerning the extent of the accident. The railroad officials can then, with a minimum of delay, arrange for the re-routing of trains and the hurrying of the wrecking and relief trains to the scene.

Canadian Notes.

The Great Northwestern Telegraph Company will soon install motor-generators in its Ottawa, Ont., office, to replace the storage battery plant. Mr. Charles E. Davies is supervisor of equipment.

Wireless Cradle — Auto-phono-cinama-cradle is the name of a French invention. For the benefit of those who cannot translate the name it may be stated that it means a combination of an automatic cradle, a phonograph and a moving picture machine. Baby's cries are recorded on a disk which starts wireless waves and the waves set the rocking mechanism in motion. The same waves start the phonograph and the moving picture machine, and ring the wireless telephone in the mother's or nurse's room.

The best way to keep posted in telegraphic and telephonic progress is to read TELEGRAPH AND TELEPHONE AGE. Subscription price $2 per year.

Telephone Pioneers of America.

BERNARD E. SUNNY.

Mr. Bernard E Sunny, president of the Central group of Bell Telephone Companies, with headquarters at Chicago, Ill., is one of the most prominent telephone executives in the United States and is yet a young man. He possesses executive and technical talent of high order, besides being a master in the art of organization and with an intelligent mind and a high personal character he has won his way through life.

Mr. Sunny was born in Brooklyn, N. Y., in 1856, and began his business career in 1872, as a messenger in the employ of the Atlantic & Pacific Telegraph Company, later becoming an operator. In 1875 he went to Chicago, there continuing in the employ of the telegraph company he had served in the East and soon became night manager of the

B. E. SUNNY,
President Central Group of Bell Telephone Companies, Chicago.

office, a promotion that was shortly afterward followed by his being advanced to the position of manager.

The telephone then in its infancy attracted the attention of Mr. Sunny. In 1879 he was offered the superintendency of the Bell Telephone Company and resigned from the telegraph to enter this new field of electrical transmission. In the subsequent merger of the Bell and Edison companies, thus forming the Chicago Telephone Company, Mr. Sunny continued as superintendent. He remained identified with telephone interests until 1888, and was closely associated with the first successful efforts to operate telephone wires underground.

In 1888 Mr. Sunny became president of the Chicago Arc Light and Power Company, which position he retained for two years.

His next change was to accept the Western management, with headquarters at Chicago, of the Thomson-Houston Electric Company, and in this responsible post he remained for two years achieving much to advance the interests of that corporation in the Western field. When the organization of the General Electric Company was brought about through the merging of the Thomson-Houston, the Brush and the Edison General Electric Companies, Mr. Sunny was called to manage its Western interests. He was made a vice-president of the General Electric Company in 1906.

In 1908 Mr. Sunny resigned his position with the latter company, and went back to the telephone service, after an absence of twenty years, as vice-president of the American Telephone & Telegraph Company and president of the Chicago Telephone Company. In addition to the offices named he is also president of the Central Union, Michigan State, Cleveland and Wisconsin Telephone Companies. His return to the telephone field was largely in response to the demand for a man who could combine executive ability with technical knowledge and a practical appreciation of the complex problems of the telephone service.

Mr. Sunny has always taken an active interest in political affairs. He was president of the Civic Federation of Chicago for four years, and effected the successful campaign for an amendment to the Constitution of the State which gave Chicago its splendid municipal court in place of the disreputable justice court system which prevailed for many years, and it will also permit the City of Chicago to secure a much needed new charter whenever the latter can be agreed upon.

He was appointed president of the Police Pension Fund by a Democratic mayor, and served for four years. and later was appointed by a Republican governor, president of the Board of Trustees of the Eastern Illinois Hospital for the Insane, which position he filled for a similar period. Mr. Sunny is a member of the American Institute of Electrical Engineers, and a few years ago was given the honorary degree of Doctor of Engineering by the Armour Institute of Technology, Chicago.

He is a director in the First National Bank of Chicago, the Chicago City Railway Company, the General Electric Company, the Western Electric Company and the Public Securities Corporation.

English Telegraph Girls.—During a meeting of the parliamentary committee in London on the subject of the application of English telegraphers —male and female—for higher pay or shorter hours, the remark was made by an opponent of the petition that the duties of female telegraphers are "purely mechanical." This remark furnishes the text for an article published in the London *Daily Express* of February 8, in which the hardships in the life of a telegraph girl are portrayed. to disprove the assertion that the duties are mechanical. The article indirectly reflects one of the results of government ownership of the telegraphs, and it is safe to say that no private company would countenance such exacting and discouraging conditions as those prevailing in the government telegraph service in England.

The Function of Crystal Detectors.

BY CLAYTON I. HOPPOUGH, VALPARAISO, IND.

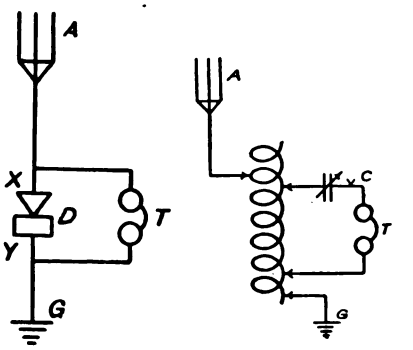
A misconception exists among many amateur and professional wireless operators regarding the use of detectors for receiving wireless signals says *Popular Electricity*. The misconception is that the detector itself is more sensitive than the ordinary current detecting devices such as delicate galvanometers, relays, telephone receivers and the like. This is an error in belief, and has probably been brought about by a lack of knowledge regarding the conditions under which the detector operates, and the exact manner in which it performs its duty.

It must first be remembered that in receiving signals we are handling currents of very high frequency. If a telephone receiver be connected to a tuning device as in Fig. 1 (the condensers and tuning coils being adjusted to a wave length of 300 meters) and we are to expect the reception of signals to result from the use of such a "hook-up," it would necessitate the diaphragm moving back and forth at the rate of 2,000,000 vibrations per second. For the diaphragm to accomplish this is mechanically impossible. Furthermore, as the telephone receiver is wound with many turns of fine wire, its self-induction is relatively great, and thus, the high frequency electromotive force generated by the action of the waves in cutting the conductors of the aerial would produce a very weak current flow through the telephone receiver. Even if the telephone diaphragm did vibrate at the rate of 2,000,000 per second, our sense of hearing would not detect the vibrations, as the greatest number of air vibrations which the ear is capable of detecting is somewhere between 30,000 and 40,000 per second. It is therefore necessary to use some appliance which will transform these rapidly reversing currents into an effect that will cause the telephone to set in motion air vibrations whose number per second are within the limits of audibility.

Probably one of the most common devices accomplishing this transformation is the carborundum detector, and as the principles governing the action of other common mineral detectors such as silicon, perikon, molybdenite, ferron and pyron coincide with those of carborundum, the statement of a few facts regarding the action of the latter may assist in understanding the action of most crystal detectors.

In 1906, General H. H. C. Dunwoody, of the United States Army, discovered that crystals of carborundum, whose chemical name is carbide of silicon, possessed the property of detecting electromagnetic waves. In the description contained in his patent application, there seems to be no explanation of why the crystals of carborundum act as a detector. Mr. G. W. Pickard in 1906 ascribed to carborundum crystals the property of unilateral conductivity; that is, that current could be made to flow freely through the crystal in one direction, but encountered great resistance when the crystal was reversed and current made to flow through it in the opposite direction. It was found also that a current passing through a carborundum crystal does not obey Ohm's law. This latter characteristic was found by F. Braun to be possessed by various minerals, such as copper pyrites, iron pyrites, galena, and copper sulphide showing traces of antimony in combination.

It is, however, to Professor Pierce of Harvard University that we are indebted for a consistent explanation of the reason for the wave detecting properties of most mineral detectors. After Professor Pierce had published the results of some of his experiments, the writer collected a quantity of carborundum crystals at random, and with the aid of delicate instruments obtained a current voltage curve which was approximately the same for seven crystals compared. In doing this each crystal was clamped between two spring electrodes and the surfaces offered for contact as well as the contact pressure was maintained as nearly constant in all cases as possible. The curve showed that the current obtained at two volts constant electromotive force through the crystal was about four micro-amperes. However,



FIGS. 1 AND 2.

the resistance of the crystals varied greatly, and three specimens, hereinafter designated as (A), (B) and (C) measured 101,790, 21,900 and 992 ohms one way respectively, and 31,960, 12,910 and 490 ohms when the current was reversed.

Attention is now invited to a brief consideration of the currents from the aerial upon a wireless receiver. They are alternating in character, flowing one way, then changing and flowing in the opposite direction. Also, as has been previously stated, they are of high frequency. Now considering Fig. 1, assume that an alternating current is attempting to flow through the carborundum crystal from X to Y. As already noted from the results obtained with the seven crystals, conditions remaining the same, more current will flow from X to Y than from Y to X. Accordingly the resultant current will partake more of the nature of a pulsating direct current than of an alternating current. These pulsating currents will cause the diaphragm of the telephone receiver shunted about the detector to be continuously pulled in the direction of the telephone magnets, because, although the pulsations may be at the rate of perhaps a million a second, the inductance of the telephone circuit changes the whole number into an effect similar to that produced by a continuous

Digitized by Google

direct current. The energy of each wave train after it has been transformed by the detector will cause one pull only upon the diaphragm, thus causing a click for each wave train, a succession of clicks forming the characters of the telegraphic code. It must not be understood from the last statement that one wave train would necessarily correspond to a dot of the code, as the whole number of wave trains per signal depends upon the rate of sending, the length of spark, the capacity of the condensers and the frequency of the current upon the primary circuit of the wireless transformer.

We have, then, by the use of a carborundum crystal obtained the desired result; that is, transformed a train of oscillations into a pulsating direct current which produces audible air vibrations. The whole action is due to the fact that the crystal is a partial rectifier of alternating current. It is from the latter fact that mineral detectors are nearly all termed "crystal rectifiers."

In the foregoing experiments by the writer an interesting comparison between the sensitiveness and resistance of the crystals was developed. Crystal (A) whose resistance was 101,790 and 31,960 ohms developed a good buzzer test, and was not sensitive enough to detect signals from a two kw. commercial station situated about 40 miles from the receiving aerial. Crystal (B) whose resistance was 29,900 and 12,910 ohms did not prove as sensitive to a buzzer test as (A) yet detected signals from the same station weakly. Crystal (C) measuring 992 and 490 ohms resistance was weakly sensitive to a buzzer test, while the signals from the commercial station were very clear and loud.

It will be noted that although the measured two-way, ohmic resistance of crystal (A) was in a ratio of 3.14 to 1, the ratio of crystal (B), which fell to 1.69 to 1 was a more sensitive detector of electromagnetic waves. It would seem from this that a great difference of the two-way, ohmic resistance of a particular crystal is not always a safe prediction of the sensitiveness of the crystal, and that a good buzzer test does not always signify that the crystal is most sensitively adjusted for wave detection.

The above results would indicate that if we could obtain a crystal in which the resistance offered to a current flowing through it one way would be equal to the resistance offered to a current passing through it in the opposite direction, it would be a more sensitive detector of electromagnetic waves than either (A) or (B). However, this is only true within certain limits, as the author, by additional experiments with other crystals than those mentioned, found that when the two-way, ohmic resistances differed by less than 20 per cent., the crystals possessed indifferent detecting qualities, regardless of contact surface, contact pressure or size of crystals.

The most sensitive carborundum crystal examined had a two-way resistance of 1212 and 461 ohms, was about the size of a pea and was jet black.

Owing to the difficulty of keeping the silicon and perikon detectors in adjustment during the application of an electromotive force sufficient to measure their resistances, using the instruments at hand, no accurate curves or resistance measurements were obtained, but a specimen of silicon with a fine steel wire contact delicately adjusted measured about 54,000 and 710,000 ohms. In the same manner, a perikon detector consisting of a piece of zincite in contact with bornite measured approximately 61,290 and 11,212 ohms resistance. The silicon firmly clamped and held in heavy contact as was the carborundum showed only twenty-one ohms resistance both ways, and a non-sensitive, heavy contact perikon detector offered thirty-two ohms resistance to a current flowing through it either way, showing that at last with the silicon and perikon detectors it is the contact rectification phenomena with which we have to deal.

In conclusion the perikon was found to be the most sensitive of all mineral detectors named in this article. However, it is very susceptible to burnouts from heavy signals or static and will easily jar out of adjustment. For general all around wireless work, the carborundum detector when assisted by about 0.3 volts external electromotive force is probably the most reliable. Although less sensitive than either the silicon or perikon, its ease of adjustment and permanent qualities when adjusted compensate for its lack of sensitiveness.

For the amateur, whose chief concern is to hear far distant stations and whose aerial is comparatively low, the perikon or silicon detectors present possibilities of wave detection not found in the carborundum. Any crystal rectifying detector is more efficient if assisted by an external electromotive force of small value. The perikon or silicon is far more sensitive than the carborundum when no external electromotive force is applied.

Western Union "Canteen" Signs.

The Western Union Telegraph Company, through the office of the engineer of equipment, has adopted three new designs of canteen signs for use in offices situated in hotels, large railroad depots, etc., where an attractive illuminated sign is desirable.

Two of the fixtures are set on brass standards, and the third is for use on wall brackets, pendants, etc. The globes are lighted by an electric light placed inside, and on the two outer faces is the company's emblem lettered in relief.

The fixtures on standards are for use on counters, shelves or other convenient conspicuous location and need no fastening, although they may be fastened if desired.

CONSERVATION TALKS—II.

BY P. KERR HIGGINS, OKLAHOMA CITY, OKLA.

A Revenue Accounting and Collecting Method.

Revenue accounting for the purpose of this article is divided into Toll and Local. This method described is designed primarily for medium and small exchanges, and has for its object, economy and efficiency by simplifying the records at the local exchange.

The object sought, is to eliminate much wasted time and material; to make system, as far as possible, "Food proof," and to give a good check on the business, which most methods fail to do. Briefly, the routine is that the contract is signed by the applicant for telephone service and filed with the commercial department where the regular routine is gone through and the order for installation issued to the plant and other departments. The telephone being installed, a record is made by the traffic department, for its own use and for the directory, the plant department also posts its records, the auditor assigns an account number, and opens an account with the new patron.

It is customary to require three months' payment in advance, as a protection to the company against the expense of installing. This also insures advance payment, which should be carefully kept up thereafter to avoid loss. When the three months' initial payment has exhausted, which should be arranged so as to occur on the last day of the month, the form of postal card shown in Fig. 1 is made up, the several items, except toll charges, being filled in, together with the telephone rental and miscellaneous charges. Care must be taken not to put any back charges, toll or local, on the cards as this is against the Post Office rules. Such data are furnished on the auditor's bill.

In a large system, an addressograph is used, and each card is put through the machine three times, placing the same information on (1) the record card, (2) the office receipt, (3) office stub. The card is then addressed in the regular manner by the Addressograph.

INSTRUCTIONS:—Check this sheet carefully with your Card Statements. Sign on the line provided, and return it to the Auditing Department. A duplicate will then be sent you for your file. RETURN THIS AT ONCE.

AUDITOR:—I acknowledge receipt of statements for all accounts as listed hereon.

.....

Manager.

FIG. 2.

Upon receipt of the post cards, the manager checks the cards with the auditor's statement, and if O. K., signs and mails it to the auditor who charges the manager's account with the total of the auditor's statement.

The manager then proceeds to post on the bills the toll charges (miscellaneous and regular charges are handled between the auditor and manager in

Digitized by Google

the usual manner), in the spaces provided. The manager then tears off the record stub at the perforation and files the stubs alphabetically in the uncollected drawer of a collection case of form divisions, (1) Uncollected, (2) Collected, (3) Suspense, (4) Rebates, etc. The post cards are now ready for mailing. If the account has no toll charges, a one-cent stamp is affixed and the card mailed; if, however, there are any toll charges, these, together with the post card, are put in an envelope, addressed and mailed. If a drop letter, one cent is affixed; if rural delivery or out of town, a two-cent stamp is affixed.

The cashier (or manager) is now ready for the receipt of payments. Subscribers are requested to bring the post card with them when paying their bills, or for adjustment, or to mail the post card with a check to cover the amount.

Each exchange is provided with a Matthews coupon machine having a cash drawer and two keys. The card drawer is kept closed, except for change, during the day, and coins, bills, and checks are dropped in the slot directly under the knife. It is found best to keep money in drawer intact and have extra change on hand. When payment is made, the post card is inserted in the machine, statement side up, the stamp is pushed back and then brought down on the card, this inks the stamp, cuts off the stub, automatically drops the stub into the cash drawer and stamps the receipt portion of the post card "Paid" which is given to the subscriber. This is the office receipt.

The stubs and cash in the drawer are balanced every evening. The stubs are then arranged according to account numbers, posted to cash report, cash deposited in bank, record cards are marked paid, dated and transferred to the collected drawer.

If, on account of error or other good reason a rebate is necessary, the cards are transferred to the rebate drawer and reported immediately to the auditor with recommendation and explanation in detail.

All collections should, as far as possible, be made in advance, but there are cases where this plan cannot, for good reasons, be used. It is well to state that in front of the "uncollected" drawer is an index arranged alphabetically, showing the telephone number, and, if necessary, the account number.

In most cases the telephone directory will, however, serve this purpose. Other than receiving payments as they come in no further action is necessary until the fifth of the month, when the cashier calls up each subscriber whose bill is unpaid and inquiries if they have received the bill, and if so when they can give it their attention, noting the replies on the back of the record card, care being taken to get the person responsible for the telephone rent. If a personal call is requested, a definite day and hour should be fixed, and such appointments kept.

Again, on the evening of the ninth or on the

REPORT OF UNCOLLECTED.

AUDITOR: ————————EXCHANGE, ——, 1912.

According to the rules of the Company I have taken the following action in regard to the subscribers whose bills were unpaid on this date.....

RULE.—The line of SUBSCRIBERS whose bills remain unpaid at————a. m., on the ————————, 191——, will have lines barred from long distance service.

No	Sub. name	Res. Bus. Rural	Tel. No	Acct. No	Exc. rental due	Tolls etc. due		REMARKS: State whether disconnected or barred and time, also give subscriber's reason for refusing to pay.

NOTE.—When exceptions to the above rule are necessary, the Manager must investigate personally each case, and use his very best judgment, protecting the Company against any possible loss in every instance. Poor judgment will reflect upon his ability to look after the Company's interest.

I certify that this report is correct in all particulars and agree to be liable for any rentals accruing on any of the above telephones after the————————inst., if, contrary to this report, the same are still in service.

I understand that all the above telephones on which the bill has not been paid by the first of next month, are to be removed and reported regularly on form————.

To the best of my knowledge, the subscribers listed are ALL the subscribers at this exchange who were in arrears in any amount on the 20th inst.

.....Manager.

We certify that we have carefully read this report, and that a copy of the same is now posted on our switchboard and that we understand that none of the above subscribers are to have service unless reinstated according to the regular rules of the Company.

.....Chief Operator.

.....Night Chief Operator.

.....Plant Chief.

.....

FIG. 3.

Digitized by Google

morning of the tenth of the month, those who have not settled their bills should be called up and reminded that the telephone will be disconnected on the eleventh day unless the bill is paid by that time.

There are exceptions to this date and this method will have to be adjusted to meet the terms of the contract, but it is only a question of education, having in view advance collections and a definite date for disconnection and removal for non-payment. On the eleventh day of the month a list of uncollected accounts (Fig. 3), is made up by the manager or cashier and turned over to the traffic and plant departments, and a certified copy, properly signed, is sent to the auditor.

When bills are due and unpaid, but good and sufficient reason exists for not disconnecting at the specified time, a statement is so made. The auditor upon receipt of the uncollected report, checks up the manager's account and draws off a balance sheet (Fig. 4), which is sent to the manager immediately. This shows in the body of the account. Where parties have left town the manager is urged to use great diligence in ascertaining the new address, this being given to the auditor. The account is transferred to suspense and followed up by the general office, if possible, to a successful termination. If a bill is not paid by the fifteenth of the month, the telephone is taken out and the company then takes such legal steps as may be necessary or advisable. The manager is required to personally visit each disconnect before the removal of telephone.

It will be seen that such a method as this, eventually dispenses with the necessity for collectors, and, in addition, reduces the amount of bookkeeping at the local exchanges, thereby making it possible to prorate the bookkeeper with another department. In addition to this, the manager is automatically checked up each month and the visits of the traveling auditor become less frequent or necessary.

The subscribers' ledger is kept at headquarters only. After the record and office stub have served

AUDITING DEPARTMENT

Gain or loss	

The manager is told that this balance is charged to him personally (he is, of course, under bond), and will not be taken off the books unless collected by him, or a definite report sent in giving good and sufficient reasons why any account or a portion of same should be rebated or transferred to suspense their purpose they may be filed or destroyed, as may seem best. Once an account is closed, the manager has no further need of any record, as he can fall back on the general office for data. Until some definite disposition is made of the account, the record is kept intact, and, if transferred to suspense, he places the record stub, etc., in the suspense drawer for reference.

The "uncollected" drawer can also be made to serve the purpose of a follow-up by using date tags to fasten on any index card where an account is to be attended to on a given date. This applies especially to overdue accounts.

Each month managers are furnished, by bulletin or otherwise, with a table showing the standing of his exchange compared with others and friendly rivalry is the result.

As a further inducement to activity in collections, etc., the regular vacation is extended in proportion to the general efficiency of the exchange. This will be explained later as the efficiency collecting is only a part of the scheme of granting vacations.

The secret of good collections is to start the account right and keep it right. This can be done by

Digitized by Google

accepting only reliable patrons and collecting three months in advance; in this way subscribers cannot get very far behind on telephone rentals. On toll rentals it is a more difficult task, and, while we give credit to most of our patrons, there are some from whom we should require a deposit, enough to protect us on service rendered. This may be five dollars, and, when this amount is exhausted, a new deposit must be made. Where a patron fails or refuses to pay his toll bills and no adjustment is possible or seems necessary, an order is issued on the traffic department to bar that particular telephone from further long-distance service until the bill is paid or adjusted. Collections from public pay stations should be made daily, thus avoiding disputes between operators and collector.

TOLL ACCOUNTING.

The following is a new method for recording and charging toll messages. It is intended to use the standard toll ticket, except that, instead of the tickets being cut and used singly, they would be printed, made up in rolls and numbered consecutively, say, in 1,000 lots. Duplicate rolls would also be provided carrying the same serial numbers, but only having printed the data necessary for the subscriber such as Form .....at ....to .....at ..... Date ..... Time filed ..... Amount toll $ ..... Messenger fees ..... Other charges ..... Total fees $.....

A roller machine, such as used in groceries, etc., would be provided permitting the original tickets to be exposed one at a time and passing over a flat, smooth surface for writing purposes, carrying at the same time, the duplicate ticket. This duplicate would pass to another roller and be retained in the machine while the original would pass out and be torn off, a special cutter edge being provided for this purpose. The duplicate would be made either by carbonizing that portion of the original to be duplicated or by having a carbon between the original and duplicate, working at right angle to the tickets on the rollers as in the typewriter or calculagraph.

The filing time could be worked in connection with the machine, but I prefer that it be written in by the operator. The machine may be made to set flush with the operator's keyboard. The machine is now loaded and ready for use, the operator enters the call in the regular manner, tears out the ticket, and proceeds to handle the call in the usual way, the method varying according to the size of the exchange, until the finished ticket arrives at the chief operator or ticket auditor, as the case may be, when the rate is checked. The chief operator, at the end of the day's business, opens the toll recording machine, tears out the used portion of the duplicate roll, and copies the charges and telephone number from the original ticket on to the duplicate and files the tickets by telephone number. The duplicate roll is then turned over intact to the commercial department, which checks the serial numbers and sees that none are missing. It then cuts them up and files the tickets carrying charges in the proper envelope (by telephone number), making the necessary entry on the face of the envelope, such as ticket number and amount.

At the end of the month, the charges on each envelope are totalled and entered on the rental post cards and mailed to subscribers, together with the duplicate slips. If, for any reason, these duplicate slips are lost, they can be made up again from the traffic record very easily, by knowing the telephone number.

The saving effected in stationery and time, to say nothing of the almost perfect record, is apparent to anyone who has gone through some of the tedious and inaccurate systems now in use.

This system also eliminates the possibility of mistakes in transferring the charges from the toll ticket to the toll bill. This system also contemplates the abandonment of the check error system and spending some of the expense connected therewith in closer traffic observation of toll calls, high efficiency which can only be had by observing, say at least 20 per cent. of all messages, an expense which is now prohibitive.

The reason for the abandonment of the check error is too well-known to require discussion, and, moreover, the speedy traffic methods now in use, make such practice impossible; however, a check should be made at irregular intervals. The only exception to this would be other company business and toll stations.

Printing Telegraphs.

BY E. R. WAKEFIELD, SEATTLE, WASH.

I would like to ask why so little information is contributed concerning the problems of the printing departments of the telegraph companies, both in the plant and traffic divisions.

There seems to be no question now but that the "Printer" has come to stay, at least as far as the Western Union Telegraph Company is concerned. Both the printer mileage and hours of operation have been greatly increased during the past year, and the installation of new circuits is still proceeding.

Since the printer was first adopted the work of those in charge of the apparatus has been largely what might be called "pioneering," for want of a better term. Each one has had to evolve a system to meet his own needs, as it was early discovered that the methods employed in handling the Wheatstone system would not answer for printer operation. All these systems have their good points and each is limited by its lack of the good points of the others. Hence there appears to be a need now for the establishment of a standard of practice for the guidance of the printer operatives. Much has been accomplished in this direction, but I believe a free discussion of printer problems would be of great benefit to all concerned.

The columns of TELEGRAPH AND TELEPHONE AGE are open to anyone who may wish to contribute information on this subject.

Telegraph and Telephone Age

Entered as second-class matter, December 27, 1909, at the Post-Office at New York, N. Y., under the act of March 3, 1879.

Published on the 1st and 16th of every month.

TERMS OF SUBSCRIPTION.

One Copy, One Year, in the United States, Mexico, Cuba, Porto Rico and the Philippine Islands . $2.00
Canada 2.50
Other Foreign Countries 3.00

ADDRESS ALL COMMUNICATIONS TO
J. B. TALTAVALL, - - - Publisher
253 BROADWAY, NEW YORK.
T. R. TALTAVALL, Editor.
R. J. WEEKS, Manager Advertising Department.

CABLE ADDRESS: "Telegage," New York.
Telephone: 6657 Barclay

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

March 16, 1912.

The Past and the Present.

We often hear the remark that conditions in the telegraph service today are not like what they used to be a few years ago and those who are wont to remind their hearers of this fact do not stop to realize that if the conditions had not changed the telegraph service would be a disgrace to this age of progress. Those who would have the old conditions still with us stand in their own light; what they need is some modern ideas.

Conditions have changed very much, it is true, but if they had not changed we would be still reading the Morse tape and cleaning battery jars, and the public would be required to pay much more than they do now for their telegrams. It is not very many years ago that the first telegraph superintendent in this country, the late James D. Reid, issued an order cautioning operators not to read by sound on pain of dismissal. Would the ultra-conservatives have those conditions today?

The telegraph is simply keeping pace with the progress of the world and it must necessarily do so or the world will not support it. The real progress is in ideas and aims and in carrying them into execution the means must conform to the end to be attained. The tape had to give way to reading by sound, and the human machine having reached the limit of its capacity has had to give way to a large extent to speedier mechanical devices. Machinery is doing the work of the world today and men merely build and control the machines. The machinery is constantly undergoing development and is becoming more and more highly specialized, and it requires highly specialized knowledge and training to operate it. That, in short, is largely the situation in the telegraph service today. Therefore, the man whose head is filled with the ideas of a quarter of a century ago is decidedly out of joint with the present. There is this to be said in favor of the telegrapher of the earlier period—he was a telegrapher in fact as well as in name, but the telegrapher of today is largely reduced to a machinery basis. The former was highly skilled since he had to do all the work himself in sending and receiving, and by his proficiency in doing his work he was graded. Nowadays, however, machinery largely performs both of these functions, and the operator has no opportunity to develop or exercise skill. Sending machines make a racket with dots and dashes and the typewriter obeys the touch of the receiving operator, and it makes no difference whether he is a good penman or not the results are the same—they are machine-made.

The machine era certainly has a tendency to make machines of men as far as their mental equipment is concerned, but at the same time it, is teaching them to be on the alert and produce the best results according to their lights. High-pressure work begets high-pressure life and telegraphers along with others are under the spell. Complaint is general as to the results of such conditions, but we suppose that there will always be complaints, no matter what the conditions may be. Conditions today are the result of progress in the world's activities and cannot be evaded, although they are nerve-racking. The only thing to do now is to improve on the nerves. They, too, must be modernized.

That the introduction of mechanical devices has worked hardships among many members of the telegraphic fraternity there is no doubt. It is for them to decide for themselves whether they shall join the procession under the new order of things. If they do not they are compelled to make way for more progressive spirits. We are living in the present, not in the past, and if we wish to make headway we must adjust ourselves to present conditions and not dwell upon the fact that things are not what they used to be—which is true—and are going to the dogs in consequence.

The Oldest Telegraph Employe.

We are constantly receiving clippings and marked copies of newspapers from all parts of the United States recording the retirement of some old-time telegrapher on pension, with the added information that the beneficiary is the oldest employe in the company's service. This information it is needless to say is in most cases added by the reporter to make the story more interesting and impressive. Of course the oldest telegraph employe exists somewhere, but it would require more time and investigation than any newspaper reporter can give to it to find the individual. If we were to refer to these separate cases in our columns it would provoke endless discussion.

Digitized by Google

Most of the clippings refer to services extending from thirty-five to forty-two years. Pensioners in this class are young men compared with many of the employes of the company, and assertions that Mr. So-and-So is the oldest employe in the telegraph service should be questioned until proof is produced.

Inquiries at the headquarters of the Western Union Telegraph Company in New York revealed the fact that the employe longest in the service, as far as the company's records show, is Mr. J. H. Seaborn, batteryman at Jackson, Tenn., who has just been retired. He entered the service in 1846 or 1847 when the first telegraph line was built through Tennessee. Mr. Seaborn is now 79 years of age.

Induction.

When a varying current of electricity flows in a wire parallel to an adjacent wire a sensitive indicating instrument—a galvanometer for example—connected to the second wire will indicate the presence of electric action, although the wire itself need not necessarily be connected directly with a source of current. This effect is called electromagnetic induction. The phenomenon was first observed and studied by Joseph Henry, the eminent American scientist.

The same effect occurs in the electromagnet of a telegraph or telephone instrument, one convolution of the wire acting inductively upon the adjacent convolutions, the practical effect of this being that the induced current tends to oppose any change in the original or inducing current—in other words, it prevents the original current from attaining its full value as rapidly as it would if the inductive effect were not present.

Induction is always present when a change takes place in the strength of the primary current; a steady and unvarying current has no inductive effect. The one essential condition to the production of induction is change in the strength of the current.

Induction cannot be prevented any more than we can prevent a pound of lead weighing a pound, but we can to a more or less extent counteract its effects, although we cannot deal with the cause. Induction takes place even on a straight wire with no other wire in its immediate proximity. Take for instance a line with a battery at one end and grounded at the other; closing the key at the battery end will start the current into the wire but the current itself will tend to induce an opposing current on the wire ahead of its own advance.

The sensitiveness of an electrical instrument—a relay for instance—is relative. The relay may not be sensibly affected by a low inductive effect, but with high-tension currents its usefulness may be entirely counteracted. A sensitive or "high-wound" relay, such as a multiplex relay, feels the effect of induction more than does an ordinary relay.

With the increasing extension and use of high tension transmission lines all over the country telegraph lines in their vicinity are suffering more or less disablement in consequence of the inductive effects caused by the rapid alternations on the power lines. In most cases the detrimental effects have been counteracted by special apparatus and in others the aid of the courts has been invoked by the injured interests to adjust the difficulties.

One of the telegraph companies is now installing special transformers on its lines between Chicago and South Bend, Ind., which run parallel to a single-phase trolley line between the two points named. The induction from the trolley line had a serious effect upon the telegraph lines, and experiments have led to the adoption of a method of overcoming the disturbing influence.

Another serious case of inductive disturbance is mentioned in another column in this issue. In this instance the induction from a high tension transmission line in Michigan has so seriously interfered with the operation of a railway's telegraph system that the railway company is seeking an injunction through the courts against the power transmission company to restrain the latter from interfering with its telegraph service on the ground that it endangers the lives of the passengers on account of the inability of the dispatchers to control the trains.

At best induction is the bane of the telegraph and there is here a wide field for the application of inventive ingenuity. As already stated the cause of induction cannot be avoided; we can only modify the effects and anyone who undertakes to deal with the problem must approach it from that direction.

What Becomes of Messengers.

"Where do telegraph messengers get to after leaving the service?" an old newspaper man recently inquired. "I have never yet heard of one turning out badly," he continued.

This gentleman has had occasion to make frequent use of the services of the young messengers, "and," he said, "I have always found them honest and good if fairly treated. One of them became a star reporter for a prominent Philadelphia paper; another has charge of an important office in New York, and a third is one of the most reliable engineers in the Pennsylvania Railroad service. The foreman of a large machine shop is a former messenger, and another commands a salary of $10,000 a year in a large automobile works.

"There have been times," he continued, "when I thought the entire lot—both of the Western Union and Postal Companies—ought to be locked up and kept on bread and water for a week, for a more mischievous set never lived. However, they get over that."

The inquirer probably knows that many railroads and industrial concerns are directed and managed by former telegraph messengers, and that they may be found in financial circles, successful and prosperous. It is because of the varied training they get while messengers that they are fitted to occupy positions of honor and trust. They all make good records after graduating from the primary class.

Course of Instruction in the Elements of Technical Telegraphy—XI.

(*Copyrighted.*)

(Continued from page 145, March 1.)

[We began in our issue for October 16, 1911, the publication of a course of instruction in technical telegraphy. The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and is divided into chapters, following one another in logical order.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.]

Circuits.

A circuit is a path composed of a conductor, or several conductors joined together, through which the current flows, from a given point, around the path, back to the starting point.

A circuit may be composed wholly of wire, or partly of wire and the earth.

A circuit is opened, or broken, when the conducting path is interrupted, or incomplete.

A circuit is closed when the conducting path is uninterrupted, or complete.

A circuit in which the earth forms a part of the conducting path is a grounded circuit.

A circuit in which the earth does not form any part of the conducting path is a metallic circuit.

The external circuit is that part outside the battery.

The internal circuit is that part within the battery.

A circuit, divided into two or more branches, is a derived or divided circuit. The branches of a divided circuit are said to be connected in parallel.

QUESTION PAPER.

(1.) A battery develops a difference of potential of 25 volts; what is the electromotive force?

(2.) In a copper and zinc combination, is zinc the negative element?

(3.) How then can the copper be the positive pole?

(4.) In a gravity cell, which element does the current start from?

(5.) What keeps the solutions separate in a gravity cell?

(6.) (a) The end copper and zinc of a battery are connected with a short wire; what represents the external circuit?

(b) The internal resistance?

(7.) What is a resistance?

(8.) Is there such a thing as a perfect conductor?

(9.) (a) When both poles of a battery are to earth does the current flow from the negative pole of the battery to the ground, or in the opposite direction?

(b) Why?

(10.) Referring to Table 1, (page 111, February 16) if copper and lead are used to develop a difference of potential, which would be the positive pole?

(11.) Can a continuous current be generated without a continuous, or constant, difference of potential?

(12.) Is the potential developed between the plates of a cell affected by the internal resistance of the cell?

Ohm's Law.

Let us suppose that a cyclist plans in a fifty mile race to ride at such a uniform speed that all his strength will be expended between the starting and finishing marks; he will be completely exhausted at the tape and will collapse at that point.

If, without the rider's knowledge, we change the condition of part of the track, substituting several yards of soft earth and metal, he will expend a good deal more force in maintaining his uniform speed over the roughened section, than was called for before the track was altered, and will therefore be exhausted before reaching the tape.

It is evident that, to complete the distance, he will be compelled to readjust his gait to the new conditions of the track, and run the race at a lower uniform speed.

If, on the other hand, part of the track be improved, the cyclist will expend less strength over the smoother section than in his calculation he had allotted to it, and at the finish will still have some energy left, which, if expended in the race, would increase his speed.

Now consider the flow of current in a circuit. It is governed by the strength of the battery and the circuit resistance, as the cyclist's speed is governed by his strength and the road conditions.

If, with a given current flow, more resistance be added to the circuit, more force will be required to overcome it, and, unless the battery strength be correspondingly increased, the current strength will be reduced.

In like manner if the resistance of the circuit be reduced, there will be an overplus, as it were, of force which will expend itself in increasing the current flow.

By Ohm's law the strength of the current varies directly as the electromotive force (E. M. F.), and inversely as the resistance of the circuit; or, in other words, anything that makes the E. M. F. of the cell greater, will increase the strength of the current proportionately, while anything that increases the resistance—either the internal resistance of the cells themselves or the resistance of the external circuit—will proportionately diminish the strength of the current.

This law may be stated in the following definite manner: The number of amperes of current flowing through a circuit is equal to the number of volts of electromotive-force divided by the number of ohms of resistance in the entire circuit; or,

Digitized by Google

$$\text{Current} = \frac{\text{Electromotive-force}}{\text{Resistance}}$$

Representing, for convenience, each quantity by the letters I, E and R; I for current, E for electromotive-force, and R for resistance, we obtain the equation:

$$I = \frac{E}{R}$$

Multiply both members of the equation by R, which will not destroy the equality of the equation,

$$E = IR.$$

Divide both members by I,

$$R = \frac{E}{I}$$

We thus have three equations which will readily give the value of the current in amperes, of the E. M. F. in volts, and of the resistance in ohms, provided two of the quantities are known in each case.

Example 1. The E. M. F. of a battery is 10 volts, the current strength .05 ampere, what is the resistance of the circuit?

Solution. $R = \frac{E}{I} = \frac{10}{.05} = 200$ ohms. Ans.

Example 2. The current strength is .05 ampere, the resistance of the circuit 200 ohms, what is the battery E. M. F.?

Solution. $E = IR = .05 \times 200 = 10$ volts. Ans.

Example 3. The E. M. F. of a battery is 10 volts, the resistance of the circuit 200 ohms, what is the current?

Solution. $I = \frac{E}{R} = \frac{10}{200} = .05$ ampere. Ans.

It is of the utmost importance that the student be perfectly familiar with these three equations, since they form the basis of electrical measurements and are indispensable to a proper understanding of the ensuing lessons. They should be carefully committed to memory.

(1) $\frac{E}{R} = I$ in amperes.

(2) $\frac{E}{I} = R$ in ohms.

(3) $IR = E$ in volts.

A New Balance for Multiplex Systems.

BY S. D. FIELD, STOCKBRIDGE, MASS.

The accompanying illustrations show a new arrangement for obtaining a balance in multiple telegraphy.

The method diminishes the error due to the presence of the usual battery resistance, and at the same time removes from the circuit the signal halting defect caused by the static capacity usually added to the equating circuit.

Fig. 1 shows the arrangement as applied to a simple straight current duplex. By following out the connections it will be seen that the first and second condensers obtain a charge during the time when the transmitter is open and no current is flowing to line.

When the key is closed, the discharge of these condensers through the equating windings of the relay, neutralizes the static charge flowing to line

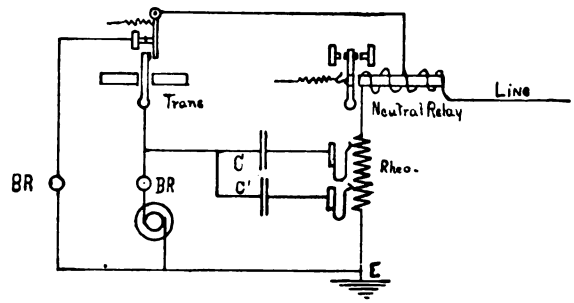

FIG. 1—APPLICATION TO SIMPLE STRAIGHT CURRENT DUPLEX.

through the line winding. On opening the key, a reverse action balances the line discharge.

Fig. 2 shows the arrangement as applied to double current work, such as the quadruplex or polar duplex.

Tests indicate that on an ordinary circuit of about 15,000 KR., a gain in signal strength of about 30 per cent. is obtained by this device, when using a signal speed of 120 words per minute.

Under this arrangement, the straight current, in its freedom from inductive disturbances on adjacent parallel circuits, together with a permissible

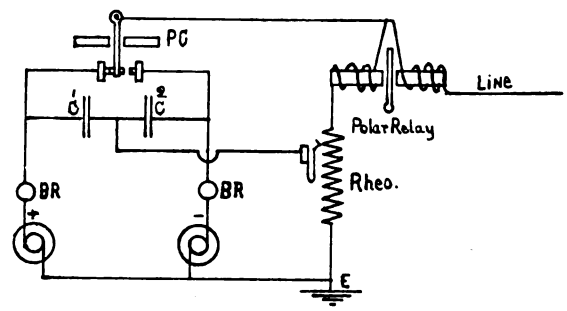

FIG. 2—APPLICATION TO DOUBLE CURRENT WORK.

use of continuity-preserving keys, becomes a strong rival of the ordinary polar duplex. Another point in its favor is the extreme simplicity of the mechanism and its consequent ease of management.

No appreciable sparking at the contacts is observable in either of the arrangements.

The arrangement is protected by a "Method" patent of the United States and other detail patents for various combinations are pending.

Mr. C. H. Walton, of Washington, D. C., in renewing his subscription for another year writes: "I think a subscription for TELEGRAPH AND TELEPHONE AGE is money well invested. A telegraph or a telephone man who does not keep up with what is doing in the two professions is dead to the world."

Telegraph Ownership.

Mr. Frederic J. Haskins, the well-known writer on economic subjects, is the author of a series of articles on telegraph ownership.

Mr. Haskins refers to the law passed by Congress in 1866, granting the right to telegraph companies in this country to build their lines over the public domain, etc., one of the provisions of which was, that the United States government might, at any time after five years after the passage of the act, purchase the lines and other property of the telegraph companies. Every telegraph company is required to subscribe to this act before it can engage in business. The whole question was brought up before Congress in 1872, when it was acknowledged that the government unquestionably has the right to acquire possession of the telegraph properties.

"The fight for the government ownership of the telegraph lines of the country and their operation in connection with the postal establishment," says Mr. Haskins, "reached its highest pitch in the early seventies. No sooner had the agreement of the telegraph companies to sell out to the government in five years from 1866 taken effect, than numerous plans were brought forward in this connection.

"The agitation, however, resulted in the passage of a law in 1874 reaffirming the right of the government to acquire ownership by purchase of the telegraph lines of the country. This act provided that the United States might, for postal, military, or other purposes, purchase all the telegraphic lines, property, and effects of any or all companies operating under the act of 1866. It was this act which was quoted by Postmaster-general Hitchcock in his recommendation of 1912 that the government acquire ownership of the telegraph lines of the country. Mr. Hitchcock is, by no means, the only postmaster-general who has recommended the acquisition of the telegraph lines by the government. The most pronounced advocate of the plan was John Wanamaker, postmaster-general under President Harrison, who made a strenuous fight to have Congress take the necessary steps to acquire the telegraph lines.

"Many objections have been urged to government ownership of the telegraph or even to government control of the message business of the country. One is the contention that the government cannot conduct a telegraph business as cheaply or as efficiently as can private enterprises. One of the reasons for opposing the government ownership of the telegraph in 1872, was the alleged fact that in point of efficiency, trustworthiness, and attention to the interests of the public, the post office system in the United States was far inferior to the postal systems of Great Britain, Belgium or Holland.

"Another argument against government ownership as advanced by David A. Wells on behalf of the Western Union, was that in every case, business conducted by the government was more dilatory, expensive and vexatious than that conducted by individuals. Mr. Wells asserted that if any corporation were to undertake to do business according to government methods, its existence, so far as public patronage was concerned, would be exceedingly limited. It was also urged that there might be a tremendous abuse of the free message business. Another objection urged was that federal ownership was inconsistent with the theory of Republican institutions. It was claimed that it would give to the government a system of espionage over the business of the country that would be subversive of the best interests of the republic.

"Likewise, it was urged that government ownership would add greatly to the patronage at the disposal of the public officers of the country, and, therefore, would hinder a clean administration of governmental affairs. It was also contended that under government ownership, the wires could be manipulated at the close of an exciting political campaign in such a way as to prevent the actual results from reaching the people.

"The most interesting investigation yet made into the telegraph business of the United States was by the Bureau of Labor in 1908. It was found that the principal telegraph companies handle four kinds of business: service and wire messages, 'C. N. D.' messages, government messages, and general business. To these might be added the press service and the transfer of money by telegraph. Service and wire messages go free and relate to the proper handling of the business of the company and the keeping in condition of the wires and apparatus. The 'C. N. D.' messages come from what is known as the Commercial News Department. They consist of stock quotations and similar business. Many business men have wondered whether the government would continue this service if the telegraph lines passed into its hands. A number of states have enacted legislation forbidding the transmission of such business, and several bills have been introduced in Congress looking to the same end.

"It is asserted by many that the United States would be making a bad bargain to acquire the telegraph companies of the country at their present-day capitalization. It is contended by those who take this view that the cost of reproducing all the lines now in existence would be much less than the cost of buying those now in operation.

"The telegraph companies," says Mr. Haskins in conclusion, "feel that their provision of night and day letter service has served to meet most of the arguments offered by the advocates of government ownership or operation."

Mr. J. P. Edwards of the office of the engineer of equipment of the Western Union Telegraph Company, Atlanta, Ga., writes:

"It not only gives me pleasure now, but it has always been my pleasure to recommend TELEGRAPH AND TELEPHONE AGE to all employes of either telegraph company with which I have been associated as *the* publication available to them, which, if they give attention to its technical articles and its editorial advice would be more productive of good to them than any other publication I know of. I shall continue advice of this kind in the future as in the past."

Word Puzzle in Telegrams.*

What is a telegraphic "word"?

This problem has worried senders of telegrams in England for many years, and *The Daily Mirror* of London, in an attempt to elucidate the mystery, learned that the problem is at present occupying the closest attention of post-office officials.

The Post Office hopes to do something to straighten out the word tangle that now exists and decide definitely what a telegraphic "word" really is. At present if you send, in a telegram the name "Newcastle-on-Tyne" it costs you but one halfpenny. If you send "Bromley-by-Bow" you must pay three halfpence. "Chapel-en-le-Frith" is one word, "Bethnal Green" counts as two words.

To the average lay mind these anomalies are beyond comprehension, and the official Post Office Guide throws but little light on the subject. According to that volume, the following are among those constituting one word in a telegram:

All words in any modern European tongue and in Latin, words ordinarily written as one or coupled by hyphens.

Names prefixed by St., O', Mac, De la. All names of towns and villages in the United Kingdom.

Initial Letters, such as H.M.S., A.M., P.M.

Yet, despite this, exception is taken to place names which are districts of a postal district, and, consequently, London suburbs boasting more than one name must pay on each.

The Daily Mirror sent the following telegram:

Father-in-law forty-five to-day; step-parents subcontracted at Newcastle-on-Tyne; wire Wood Green.

This message totals actually seventeen words and seven hyphens. The Post Office accepted it as ten words, charging two for Wood Green, because it was part of the London postal district. Another telegram was addressed to Green-street, Bethnal Green. The clerk demanded one halfpenny for each word in Bethnal Green, despite *The Daily Mirror's* protestations that this place was a separate parish and borough, and was certainly in the United Kingdom. The overseer at the Ludgate Circus Post Office was called into the discussion. He was official and adamant, so *The Daily Mirror* continued its inquiries at the General Post Office. There the secretary explained that as far as the Post Office is concerned a postal district is a town, and any part of that district merely part of a town. To the Post Office, the City of Westminster, has no more importance than Shepherd's Bush; both are mere parts of London.

It was admitted that Bethnal Green was an historic parish, once a village, now a borough, but it also happened to be in the London postal district, and consequently, must pay the penalty and be charged two words.

"The rule," the secretary said, "is a continual bone of contention, and we are, at the present time, considering in what way it can be modified. But it is full of difficult points. If Tulse Hill, the district, be admitted as one word, why not Tulse Hill, the thoroughfare, and if that, why not High Street, or any name of a road."

It was suggested that any two-word named place at present just outside the London district would, upon being absorbed, lose its right to be transmitted as one word. Ponders End was suggested as an example.

"No," said the secretary, "that is not the case; once a name has been admitted as one word it always retains that right."

And the rule remains for the time being, at any rate, that no matter how many words the name of the postal district may contain, it counts but one, Any part, however, of that postal district must pay for its name at the usual rate.

*From *The Daily Mirror*, London.

Rapid Restoration of Telephone Service in Birmingham, Ala.

On Sunday morning, January 14, fire completely wrecked the four upper floors of the building of the Southern Bell Telephone & Telegraph Company in Birmingham, Ala., and the entire toll switchboard, used for long distance connections and located on the fifth floor, became a complete loss. The local switchboard and the associated frames and racks on the second and first floors, respectively, were not injured by the fire, but some damage was done by the water coming through from the other floors. Telephone communication was established with the Hawthorne, Ill., factory of the Western Electric Company the same afternoon, with the result that within forty-eight hours a complete new toll switchboard equipment, consisting of eight two-position sections with miscellaneous cable, was shipped by express to the scene of the fire.

Meanwhile, an installing force was put to work on Monday morning, January 15, to assemble the temporary toll equipment forwarded from Atlanta, and by 1:30 p. m., toll communication was restored in temporary quarters obtained for that purpose. Owing to the damage done to the local switchboard equipment, a considerable amount of work was necessary; but by January 23, 70 per cent. of the local service was restored and the remainder on the following day. The new toll switchboard arrived in Birmingham promptly, and was put into service at 2 o'clock Monday morning, January 29, giving the telephone company a new, up-to-date toll equipment in fifteen days.

Got Down to Facts.—One of the telegraph officials who had been annoyed by newspaper men in their endeavors to obtain an official statement from him as to the condition of the wires after a recent severe storm, in desperation replied that there seemed to be no trouble between New Rochelle, N. Y., and Stamford, Conn., and that business between those points was moving with accustomed regularity. The statement verbatim appeared in one of the newspapers. Now the question is how much business does New Rochelle have for Stamford in the course of a day.

The Ground Connection in Lightning Protective Systems.*

BY E. E. F. CREIGHTON.

GENERAL ELECTRIC COMPANY, SCHENECTADY, N. Y.

This matter can be clarified only by an analysis of the requirements in each case. Before that is done, however, it is useful to note that the three main elements of interest in an earth connection are the resistance, inductance, and a condition which, for want of a better name, may be designated as the electro-static capacity factor or equalizing connection.

In regard to the resistance, its constancy may be affected, either gradually, by droughts, freshets, freezing and such other changes as naturally attend the seasons; or suddenly, by the heat given out by an electric current passing to ground. Furthermore, in regard to the resistance of an earth connection, its laws differ from the ones we are accustomed to use. For example, we are accustomed to think that if the area of cross-section of the conductor is increased, the resistance will be correspondingly decreased. However, doubling the area of a pipe-earth by increasing the diameter does not reduce the resistance to earth by one-half; in fact, by such a change, the resistance to earth may be decreased by only a small percentage. If not in a reduction of resistance, what, then, is gained by an increase in area? This is a question that must be answered. Also how can the earth resistance be reduced? And why not by doubling the area of a single earth-plate?

In regard to the earth connection, there is still another factor of an unusual nature that must be taken into account, viz., its permanency or life. When a conductor is installed overhead, its oxidation is of negligible value even after many years of use and the electro-chemical action is sensibly nil. In an earth-connection, however, conduction is naturally by electrolysis, which produces a dissociation of the materials; and, furthermore, the metal parts are subject to the chemical action of the soluble ingredients of the moist earth. Still further there is a great difference in wear on the earth-plate, depending on whether the current is alternating or direct.

In regard to the second main division, viz., the inductance of earth-connections, the three main factors are, length of the conductor, loops in the conductor, and multiple conductors.

There is still the third division which has been designated as the electrostatic capacity factor.

It is convenient not to follow the exact order given in the foregoing outline. It seems desirable to state, as briefly and definitely as may be done, the general laws concerning earthing, give instructions for making a pipe-earth, and then later give detailed data on which the laws are based.

After a depth of several feet in the conducting stratum has been reached, each additional foot decreases the total resistance by one divided by depth in feet. This is explained later.

*Abstracts from "General Electric Review."

Practically all the resistance is in the earth in the immediate vicinity of the pipe. This resistance depends on the specific resistance of the material. The specific resistance depends on the amount of moisture and electrolyte in the moisture. To get the lowest possible resistance, pour strong salt water around the pipe.

When it is desired to lower the resistance to earth below that of a single pipe-earth, drive others at distances of not less than six feet. Then the total conductance is only slightly less than the sum of the individual conductances, and the total resistance is the reciprocal of the total conductance. For uniform condition of soil, the approximate rule may be stated: That two pipe-earths connected together give one-half the resistance of one, ten pipe-earths give one-tenth the resistance of one, and so on.

For distances between pipe-earths up to one foot, the resistance increases rapidly. For every additional foot, the added resistance becomes less and less. At a distance apart of six feet, the resistance has reached nearly a constant value. Stated otherwise, the resistance between two pipe-earths at any distance apart greater than six feet is nearly equal to the sum of the isolated resistances of each.

Since the resistance of a pipe-earth lies mostly in the immediate vicinity of the pipe, the greatest potential drop when the current flows, will also be concentrated there. Heating and drying out will tend to magnify this.

The quantity of electricity that can be passed through a pipe-earth, without materially changing its resistance, increases directly with the wetness of the earth in contact with the iron, and the area of the iron surface exposed to the passage of the current; and decreases as the resistance of the earth in contact with the pipe increases. Certain critical values of current may be carried continuously by a pipe-earth without varying the resistance. The higher the current above this critical value, the more rapid the drying out. To increase the ampere-hour capacity, keep the pipe-earth wet with salt water.

The resistance of a pipe-earth does not decrease in direct proportion to the increase in diameter of the pipe. Two pipes driven side by side and connected together will have only slightly less resistance to earth than one pipe; it is, therefore, not surprising that a pipe two inches in diameter has a resistance only about six per cent. to twelve per cent. less than a pipe one inch in diameter.

Make the connecting wire as short as possible by taking as direct and straight a path as possible. The objection to sharp corners lies entirely in the fact that it is longer around two sides of a triangle than it is along the hypothenuse. A curved turn is shorter than a right-angled turn, but it is not as short as the hypothenuse.

Loops in the lead introduce unnecessary impedance to high frequency impulses.

The inductance of a conductor to high frequency may be said to decrease with the increase of surface. A hollow metal tube conducts as well as a solid wire of the same circumference. A flat strip is an economical way of getting large surface with

Digitized by Google

a small weight of metal. The minimum degree of inductance with the minimum weight of metal is obtained by using separated parallel wires. Copper is best on account of its conductivity and durability, but since only the surface layer of metal carries the current, galvanized iron is permissible in some cases.

An earth connection is necessarily made by electrolytic conduction. To obtain a low resistance, it is therefore necessary to have electrolytic moisture in contact with the earth-plate, or, lacking thus a fair degree of conductivity, it is necessary to have a very large area of cross-section for the current. One finds no dry earths that are conductors. If the earth contains no soluble substances which conduct electricity it is necessary to add an electrolyte. The one precaution in choosing an electrolyte is to avoid one which attacks chemically the metal conductor.

It is impossible, as many know, to make a rule or practice to cover all cases; but, the general practice of using pipe-earths can be justified in nearly every case of earth-connection. Coke, so often recommended for earth-connections, is not a good conductor in itself. It attracts and holds moisture, to be sure; but since that moisture usually does not contain an electrolyte in solution, it leaves the earth-connection with high resistance. From every point of view the iron pipe-earth is to be recommended,—on the basis of first cost, ease of inspection, resistance, care, measurements, etc. Iron is the cheapest available metal; its use in water-mains has thoroughly proved its serviceability even when embedded in salty marshes. Salt or washing soda is to be recommended as electrolyte. While washing soda has less chemical effect on iron than salt, the resistance is higher. In the majority of conditions, salt is preferable.

All the fanciful ideas in "grounds" may be classed with the platinum points for lightning rods. They are both miserly ways of burying money.

Just plain pieces of standard one- to two-inch pipe, driven as much over six feet as is convenient, are best. Solid metal spear-heads on a pipe, and sleeve joints which make holes larger than the diameter of the pipe, increase the contact resistance enormously. If for any reason they are used, special precaution should be taken to fill up the space between the pipe and the earth by an abundance of salt water. If the pipe drives with too much difficulty a solid crow-bar will usually open up a hole. If there is no stand available for starting a pipe eight feet or more long, a shorter pipe, slightly larger in diameter, may be driven several feet and then withdrawn to make a start for the longer pipe.

A basin should be scooped out of the earth at the surface around the pipe, and salt brine poured in. The amount of salt water needed depends on the local conditions of the soil. Where the resistance of a pipe-earth is less than 100 ohms without salt, a bucket full of brine may suffice; where the pipe-earth does not reach moisture below, several bucketfuls may be necessary. Finally, a few handfuls of crystal salt should be placed around the top of the pipe in the basin. Whether the basin is to be filled with dirt, or made permanent by the use of a tile with a cover, depends upon the importance of the earth-connection.

It has been the practice to use a buried coil of copper wire for a local ground near the relays on signal circuits. A number of signal engineers have recognized the value of using a rail for an earth connection and have used an extra gap between a rail and the local ground or earth. Measurements of the relative resistance of the local earth and a rail show that a rail, in spite of its position on wooden ties and rock ballast, has only a small fraction of the resistance of a local earth-plate. Furthermore, the rails, on account of their length, gather in the radiating earth-currents of a lightning stroke. It seems reasonable to presume that an induced potential from electrostatic charges will exist principally between the overhead wires and the rails. Protection should therefore be provided between these two circuits. So far as the writer knows, no reason is evident why the ground terminal of a lightning arrester should not be connected directly to one rail without the use of a local earth-plate. So long as the lightning arrester is shunted across the coils and contacts to be protected, the inductance of the length of rail is a factor that does not enter the problem of protection. At any rate, even when a local ground is used, there should be a lightning arrester connection to a rail.

A pipe-earth or rod-earth is usually sufficient. The earth-connection should be capable of carrying the current of a series arc circuit without drying out. In case of such an accidental cross, the fuses protecting the instrument will not, and should not, melt and open the circuit. It is necessary tor the earth connection to maintain a fair degree of conductivity in order that the potential at the telephone receiver may be kept down to a safe value.

Rapid Work in Handling Telegram by Telephone.

"As an illustration of the speed of the Western Union Telegraph service in connection with the present practice of receiving and delivering messages by telephone," says the *Telephone Review*, "a lady in White Plains, N. Y., recently telephoned a telegram to the local joint telephone and telegraph office, for a point in southern Virginia. An answer was received over the telephone in exactly thirty-six minutes from the time the original message was filed. This so astonished the sender that she at first refused to accept the answer as genuine, saying that it was impossible to get an answer from so distant a point in that time, and the local office must have received the message given to her as a reply, before her message reached its destination.

"She finally became satisfied, however, that the answer was really sent in reply to her message.

"It can readily be seen that had the delivery of the message depended on messenger boys, the thirty-six minutes or more, would have been thus consumed with no time left for transmission between White Plains and Virginia."

Telephone Lines.*

A telephone line consists of two conductors, one of which may be the earth; the other always is some conducting material other than the earth —almost universally a metallic wire. Both conductors of a line may be wires, the earth serving as no part of the circuit, and this is the best practice. A line composed of one wire and the earth is called a grounded line; a line composed of two wires not needing the earth as a conductor is called a metallic circuit.

In the earliest telephone practice, all lines were grounded. The wires were of iron, supported by glass, earthenware, or rubber insulators. For certain uses, such lines still represent good practice. For telegraph service, they represent the present standard practice.

Copper is a better conductor than iron, does not rust, and when drawn into wire in such a way as to have a sufficient tensile strength to support itself is the best available conductor for telephone lines.

In the open country telephone lines consist of bare wires of copper, of iron, of steel, or of copper-covered steel supported on insulators borne by poles. If the wires on the poles be many, cross-arms carry four to ten wires each and the insulators are mounted on pins in the cross-arms. If the wires on the poles be few, the insulators are mounted on brackets nailed to the poles. Wires so carried are called open wires.

In towns and cities where many wires are to be carried along the same route, the wires are reduced in size, insulated by a covering over each, and assembled into a group. Such a bundle of insulated wires is called a cable. It may be drawn into a duct in the earth and is then called an underground cable; it may be laid on the bottom of the sea or other water and be called a submarine cable; or it may be suspended on poles and be called an aerial cable. In the most general practice each wire is insulated from all others by a wrapping of paper ribbon which covering is only adequate when very dry. Cables formed of paper-insulated wires, therefore, are covered by a seamless continuous lead sheath, no part of the paper insulation of the wires being exposed to the atmosphere during the cable's entire life in service. Telephone cables for certain uses are formed of wires insulated with such material as soft rubber, gutta-percha and cotton or jute saturated with mineral compounds. When insulated with rubber or gutta-percha, no continuous lead sheath is essential for insulation, as those materials, if continuous upon the wire, insulate even when the cable is immersed in water. Sheaths and other armors assist in protecting these insulating materials from mechanical injury.

A wire supported on poles requires that it be large enough to support its own weight. The smaller the wire, the weaker it is, and with poles a given distance apart, the strength of the wire must be above a certain minimum. In regions where freezing occurs, wires in the open air can collect ice in winter and everywhere open wires are subject to wind pressure; for these reasons additional strength is required. Speaking generally, the practical and economical spacing of poles requires that wires, to be strong enough to meet the above conditions, shall have a diameter not less than .08-inch, if of hard-drawn copper and .064-inch, if of iron or steel.

Lines whose lengths are limited to a few miles do not require a conductivity as great as that of copper wire of .08-inch diameter. A wire of that size weighs approximately 100 pounds per mile. Less than 100 pounds of copper per mile of wire will not give strength enough for use on poles, but as little as ten pounds per mile of wire gives the necessary conductivity for the lines of the thousands of telephone stations in towns and cities.

Grouping small wires of telephone lines into cables has the advantage over open lines of allowing less copper to be used, of reducing the space required, of improving appearance, and of increasing safety. On the other hand, the same grouping introduces negative advantages. It is not possible to talk as far or as well over a line in an ordinary cable as over a line of two open wires. Long-distance telephone circuits, therefore, have not yet been placed in cables for lengths greater than 200 or 300 miles, and special treatment of cable circuits is required to talk through them for even 100 miles. One may talk 2,000 miles over open wires. The reasons for the superiority of the open wires have to do with position rather than material. Obviously it is possible to insulate and bury any wire which can be carried in the air.

A telephone line composed of two conductors always possesses four principal properties in some amount: (1) conductivity of the conductors; (2) electrostatic capacity between the conductors; (3) inductance of the circuit; (4) insulation of each conductor from other things.

*From *Telephony*, by McMeen & Miller.

Bound Volumes of Telegraph and Telephone Age.

TELEGRAPH AND TELEPHONE AGE for 1911 covers a period of great activity in telegraph and telephone development and contains a complete record of all important events in these lines, besides much other interesting and valuable matter of general and technical interest. The volume is well worth preserving by students and subscribers, as its contents will be frequently referred to on account of their important character.

Bound volumes are now for sale at the publication office of this journal, 253 Broadway, New York, at $3.50 per volume, express charges collect. These volumes are neatly bound in cloth and will be found very handy for the library.

Mr. S. Gray of the Western Union Telegraph Company at Wilmington, Del., in renewing his subscription writes: "I do indeed want the TELEGRAPH AND TELEPHONE AGE as I read every part of it and find it of the greatest interest to me."

Poles Purchased in 1910.

In our issue for October 16, 1911, note was made of the preliminary statement issued by Census Director E. Dana Durand, Washington, D. C., as to poles purchased in the United States in 1910. The full report on the subject has just been issued by the Bureau of the Census, and, from this report, we abstract some additional facts of general interest.

The demand for wooden poles, now amounting to nearly 4,000,000 annually, is supplied principally from three different sections of the United States, the northern white cedar region of the lake states, the chestnut region of the eastern portion of the United States, and the western red cedar region of the Northwest, including Idaho, Washington and Oregon. Southern white cedar, or juniper, is found mainly in North Carolina, Virginia and New Jersey. At present the largest part of the cedar used is cut in the lake states, but the indications are that the Northwest will be called upon to supply a constantly increasing proportion.

The qualities most desired in a pole timber are durability, strength, lightness, straightness, and a surface which will take climbing irons easily. The various species of cedar combine these qualities in a high degree. Next to cedar, chestnut, oak and pine were the leading woods drawn upon. The demand for these four species grows greater each year. Over 80 per cent. of all poles reported were of cedar or chestnut, cedar alone supplying nearly 62 per cent. of the total. The number of cedar poles increased slowly during the last few years up to 1909, but shows a slight decrease in 1910. The use of chestnut poles fell off considerably from 1907 to 1908, but, since the latter date, has again increased.

The number of oak poles purchased shows a heavy increase, the number purchased, in 1910, being more than three times that reported in 1907. Various species of oak are utilized in different parts of the country, the more durable varieties of the white oak group being preferred. The number of pine poles has shown a slight increase for each year, except 1908. Several species of Southern yellow pine are used to considerable extent, principally in the Southern States. In the West, another species, the Western yellow pine, is reported. The latter is seldom used for poles without preservative treatment.

The number of cypress poles purchased seems to be falling off, the number reported for 1910 being only about three-fourths as great as in 1907. Cypress poles are cut only in the Southern States, mainly in Arkansas and Missouri. The use of Douglas fir in the Northwest is growing rapidly. Over 56,000 Douglas fir poles were reported in 1910, as compared with about half this number in 1909, and less than 16,000 in 1907. Poles of several other kinds of woods were purchased in quantities of less than 50,000, of which tamarack, redwood, osage, orange, spruce and juniper were the most important. More than a dozen other woods were utilized to a relatively small extent.

The telephone and telegraph companies, which are the principal consumers of poles, reporting 73.2 per cent. of the total number used, purchased 84,195 fewer poles in 1910 than in 1909. The electric railway and electric light and power companies, on the other hand, purchased 105,678 more poles than in 1909, while the steam-railroad companies purchased 110,471 more poles than in the preceding year.

More than one-half of the poles purchased are from 20 ft. to 30 ft. long, this being the length most commonly used by the telegraph and telephone companies. About one-fifth are from 30 ft. to 40 ft. in length, and one-twentieth from 40 ft. to 50 ft. Only about 1 per cent. of the poles purchased exceed 50 ft. in length. Poles of less than 20 ft. in length are used largely by the rural telephone companies, which report a considerable variety of woods, prominent among which is oak.

The increase from 1909 to 1910 in the total number of poles purchased was 3.5 per cent. The largest increase for any of the several classes, was that for poles over 50 ft. in length, 23.5 per cent., and the next largest, that for poles from 40 ft. to 50 ft. in length, 16.9 per cent. A slight decrease is reported for poles from 20 ft. to 30 ft. long.

For a number of years past, experiments have been carried on by private parties, and by the United States Forest Service, with a view to finding and perfecting methods of preventing such decay, and, it may be stated, that it is possible, through the proper application of certain preservatives, to increase the life of a pole from 50 to 100 per cent. The practice has proved a success economically. Not only does it lengthen the life of the pole, but it makes possible the utilization of many cheap local woods which, without preservative treatment, would be valueless for the purpose, thus reducing the cost of poles and transportation charges. In the principal European countries, the practice of pole preservation is much more common than in this country, nearly every pole receiving a penetrating treatment with some preservative before being set. The economy of the process has been so well established that as it becomes generally understood, the percentage of treated poles reported in the United States, will no doubt rapidly increase, and the methods used become more effective each year. The preservatives most commonly used are creosote oil, a solution of zinc chloride and various proprietary preparations, usually antiseptic oils of low volatility.

The increase in the practice of really effective pole preservation in the United States has been retarded by the lack of pole-treating apparatus applicable to the needs of the small consumer. As a result, poles have been treated mainly by methods which do not require the use of a special treating plant, and which add but few years to their service. The usual method is that of painting the lower end of the pole with the preservative.

A somewhat more effective method is that of dipping the pole in an open tank containing the preservative. By this operation all seasoning checks are thoroughly penetrated. A variation of this method is to stand the poles upright in a bath of

Digitized by Google

the preservative, making the wood of the butt end of the pole decay-proof by the absorption of large quantities of the oil or solution, through the action of a partial vacuum in the wood cells created by the alternate raising and lowering of the temperature of the bath. Satisfactory plants have been devised for this purpose which are economical for firms using considerable numbers of poles annually.

In parts of the South, conditions are so favorable to decay, that it is desirable to treat the entire pole, and both commercial and private plants have been established for this purpose. The poles are placed in a closed cylinder, and absorption of the preservative is secured by the use of pressure. Large numbers of pine poles have been treated by this method, which is found to be the most effective.

By far the larger part of the treated poles were treated after purchase, the increase in the number treated after purchase during the past few years being much more rapid than that in the number treated before purchase. The electric railway and electric light and power companies have been especially active in pole preservation. These companies treated nearly 30 per cent. of their poles, while the telephone and telegraph companies and the steam-railroad companies each treated less than 20 per cent. of their poles. These percentages indicate a large gain for each class of purchasers, except the steam railroads, which treated 31.1 per cent. of the poles purchased by them in 1909.

Although the number of treated poles reported, is growing rapidly each year, most of these poles receive a merely superficial treatment which adds only a very few years' service. The figures for 1910 indicate that a larger proportion of the poles were treated during that year by the brush and open-tank methods, than in the preceding year. Future progress in pole preservation should show not only increases in the number of poles treated, but an increasing use of the more effective methods of preservation.

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. The review of Maver and Davis' book. "The Quadruplex," was completed in our issue for February 16, and the next book to be taken up and treated in like manner is "Electrical Instruments and Testing," by Norman H. Schneider, with chapters on testing wires and cables and locating faults, by Jesse Hargrave, a well-known and capable electrical engineer. These subjects will no doubt prove of great interest to students, as they are timely and important, and each student should have a copy of the book at hand in order to follow intelligently the study of the subjects under consideration.]

GALVANOMETERS.

What do the primary laws of electricity teach?

What is the effect upon the current of increasing and decreasing the E. M. F. and resistance?

If the deflection of the galvanometer needle is too great, how can it be decreased, and what instrument is used for the purpose?

How are the coils of a rheostat connected?

Why is the deflection of the galvanometer needle reduced by the addition of resistance to the circuit?

Upon what does the sensibility of a galvanometer depend?

If we desire to measure low resistances, should the resistance of the galvanometer be high or low?

What is the meaning of the term "ampere-turn"?

If a galvanometer has one coil of one turn of wire and another coil of 100 turns, would a current of one ampere in the first coil cause a lesser or greater deflection of the needle than a current of one-hundredth of an ampere in the second coil. State the reason for the result.

Why are galvanometer coils usually wound with a large number of turns of fine wire?

What is the effect upon the needle of multiplying the number of turns?

What is the object of the windings of a galvanometer—to get resistance or ampere-turns?

If the needle gives a deflection of ten degrees with a current of ten milliamperes through its coil, would a current of twenty milliamperes give a deflection of twenty degrees? If not, state the reason.

If the galvanometer coil is made large and the needle very small, what is the effect?

[The various kinds of galvanometers will be taken up for consideration in the next installment of these questions.]

Induction from Michigan Transmission Lines. The Eastern Michigan Power Company which is utilizing the Ausable River in Michigan for electric power purposes, and built a transmission line to Bay City, Saginaw and Flint, supported by steel towers, on February 1 turned on current at approximately 140,000 volts pressure. The line parallels the Detroit & Mackinaw Railroad between Emery Junction and Pinconning, a distance of twenty-nine miles, and the induction from this high voltage line completely paralyzed the wires of the Western Union Telegraph Company, and the Detroit & Mackinaw dispatcher wires between these two points. An injunction applied for by the railroad company restraining the power company from interrupting the telegraphic service, thereby endangering the lives of passengers on account of the dispatchers having no control of their trains, is now pending in Judge Connine's court in Tawas City, Mich.

Censorship in Santo Domingo. — The Santo Domingo government has established a censorship on private telegrams to and from that republic.

Mr. W. C. Black, superintendent of the Postal Telegraph-Cable Company of Denver, Col., in renewing his subscription, writes: "TELEGRAPH AND TELEPHONE AGE is the one journal that we cannot do without."

The Military Telegraph Pension Bills.

Mr. A. A. Zion, of Indianapolis, Ind., chairman of the legislative committee of the Society of the United States Military Telegraph Corps, advises us that "as chairman of the legislative committee, appointed by President Col. W. B. Wilson, at the last meeting of the association for the purpose of securing action on the part of Congress to pension the military operators who served in the Civil War, proper bills to secure this result have been introduced in both the Senate and the House and are now in the hands of the committees on pensions.

"We have made personal appeal to each and every member of the House of Representatives and the Senate," says Mr. Zion, "asking them to favor our bill and they have been made thoroughly familiar with our cause. The congressional committee has also received the hearty support and co-operation of every member of our association by appealing to their respective representatives and senators to use their best efforts to secure favorable report from the pension committees and support of the bill. We have also appealed to President Taft and other prominent and influential men throughout the country, including several governors of states, asking them to assist us in our efforts for the passage of the bill by their taking the matter up direct with members of the pension committees and members of congress. We have received an unqualified endorsement of our cause by members of congress and those who have been appealed to to assist us, and we have every reason now to believe that Congress, at this session, will pass the bill.

"The members of our committee, consisting of Mr. E. Von Eye, Crawley, La.; Mr. Frank B. Knight, Dallas, Tex.; Mr. Ten Eyck Fonda, Omaha, Neb.; Mr. M. F. Robinson, Sanford, Fla.; Mr. R. H. Bohle, St. Louis, Mo., and Mr. J. J. Fowler, New Orleans, La., have spent a great deal of time in assisting in this work and have accomplished a great deal of good. President Wilson has spent considerable time at Washington conferring with congressmen and the pension committees, and is keeping in close touch with this matter, and secretary David Homer Bates has rendered some very valuable assistance by writing personal letters to several of his prominent friends in Washington, which will no doubt prove very beneficial.

"I want to inform the members of our association," Mr. Zion says in conclusion, "that they can rest assured that every possible effort is being made to secure favorable action on the part of Congress and that no stone will be left unturned to secure them the benefits that they have so long been deprived of. It is surprising how many members of congress have advised us that they are in hearty sympathy with our cause and that when given an opportunity, they will use their best efforts to secure the passage of the bill."

Proposed National Commercial Organization.

In his message to Congress on December 7, 1911, President Taft expressed his belief that it would be of great value to have "some central organization in touch with the associations and chambers of commerce throughout the country, and able to keep purely American interests closely in touch with commercial affairs."

In a statement issued March 1, Mr. Taft announced that he had instructed the Secretary of Commerce and Labor to take the necessary steps to initiate as soon as practicable at Washington a conference of delegates from organizations which are engaged in the promotion and development of commerce and industry in their respective districts, such conference to consider the establishment of a representative national organization for commercial development, and to outline the principles by which it should be governed. "It is obvious," he says, "that by some means immediate relation between the government activities and the commercial and industrial forces of our country must be established if we propose to enjoy the full advantage of our opportunity in domestic and foreign trade."

In compliance with these instructions Mr. Charles Nagel, Secretary of the Department of Commerce and Labor, has called a conference of such delegates to be held at Washington on April 15.

Government Ownership of Telegraph in Canada.

During a recent discussion in the Canadian parliament at Ottawa, Ont., on the subject of government ownership of Canadian telegraph lines. Mr. J. E. Armstrong argued that the telephone and telegraph services could be handled with greater economy through the post office department. The proposition, he said, was along the lines of the Hydro-Electric Commission. The commission brings the wires to the municipalities and in like manner the trunk lines for Telephones could be built from city to city and municipality to municipality. The commission favored government ownership of telephone and telegraph lines as it could more readily distribute power to the farmers by using the same poles. [Nothing is said about the troubles from induction by running telegraph and telephone lines on the same poles with the power wires.]

Hon. Rodolphe Lemieux favored the proposition. He said that much of the news received in Canada from the mother country was more or less tainted because of coming through American services.

A. I. E. E. Convention.—The annual convention of the American Institute of Electrical Engineers will be held at the new Copley-Plaza Hotel, Boston, Mass., on June 25-28.

Every one engaged in telegraphy and telephony should be a constant reader of TELEGRAPH AND TELEPHONE AGE. It gives the latest news in both these fields. Subscribe now. Subscription price, $2.00 per year.

The Transmitter Battery

IN the early days of the telephone, considerable difficulty was experienced in devising a transmitter which would regulate the current in the transmitter circuit, in unison with the sound waves until Edison, in 1877, invented the carbon transmitter.

This invention was a long step forward in the perfection of the telephone, and the improvement in transmission was marked. If you are using a type of Primary Battery that supplies a fluctuating current, you can effect an improvement in transmission approximating that brought about by the invention of the carbon transmitter, by using EDISON-BSCO Primary Cells for talking circuits.

EDISON-BSCO Cells are eminently suited for this service, because they do not polarize and are of extremely low internal resistance; therefore, they give perfectly uniform voltage throughout their entire life on transmitter work, whereas, dry cells quickly polarize, even at low discharge rates, resulting in fluctuation in the potential and reduction of the intensity of the magnetic field.

EDISON-BSCO Cells are now made in various styles, ranging in capacity from 200 to 400 ampere hours, or sufficient to give continuous service on way station 'phones, for instance, of from two to five years or more under average conditions of service on one charge, without renewal or other attention.

The strongest argument favoring the use of these cells is the improvement effected in the service, for the reasons explained above, but aside from this, the question of economy deserves consideration. The cost of active material consumed by EDISON-BSCO cells represents only about one-third the cost of dry cells, on similar circuits, and the long life of the Edison cell reduces the expense for labor to the minimum.

The Railroad.

Telephone Dispatching on Central Vermont.—A telephone train dispatching system has been installed on the New London division of the Central Vermont Railroad. Two dispatching districts on this road—Northern and Southern—are now equipped with telephone dispatching equipment. Mr. M. Magiff, St. Albans, Vt., is superintendent of telegraph.

Pennsylvania Telegraphers Visit Lehigh University.—Two hundred employes of the telegraph and telephone department of the Pennsylvania Railroad met at Lehigh University, South Bethlehem, Pa., recently, and listened to addresses by Professor W. S. Franklin on the "Gyroscope," and Mr. A. L. Erwin, on "Morse and Multiplex Telegraph Apparatus."

Chicago Meeting of Railway Telegraph Superintendents.

At the joint meeting of the Eastern and Western Divisions of the Association of Railway Telegraph Superintendents, at Chicago on March 20, many matters of special interest will be presented for consideration, including the arrangements and programme for the annual meeting of the Association, which is to be held at the Waldorf-Astoria in New York, in June. The Entertainment Committee, of which L. S. Wells, superintendent of telegraph of the Long Island Railroad, New York, is chairman, is actively engaged in arranging matters in connection with the convention and entertainment and there is every indication that the meeting will be a successful one and largely attended. The committee will leave nothing undone that will in any way aid in the realization of their efforts to make the convention a complete success. Much credit is due Mr. L. B. Foley, superintendent of telegraph, Lackawanna Railroad, New York, acting chairman of the Entertainment Committee, in the absence of Mr. Wells on account of illness, for the progress that has been made in this regard.

Another matter that will probably be brought to the attention of the joint meeting at Chicago will be that of cost of maintenance, rates of pay, statistics, etc., in train movement service since the adoption of telephone train dispatching. There is urgent need for data of this character and while the subject has been discussed at former meetings nothing definite has been formulated. The whole matter of compilation is in the hands of a special committee, consisting of Mr. U. J. Fry, of the Chicago, Milwaukee & St. Paul, Milwaukee, Wis.; Mr. W. W. Ryder, of the New York Central Lines, Chicago, and Mr. W. F. Williams, of the Seaboard Air Line, Portsmouth, Va., and it is expected that the committee will be ready to report action at the general meeting in June.

In our issues for February 1, February 16, and March 1, we printed reports from many railway telegraph superintendents on the extension of telephone train dispatching on their respective lines, and the records show that it is a live subject with the railroads, and all authorities agree that it is only a question of time when the telegraph will be entirely superseded by the telephone as a means of dispatching trains and transacting other classes of railroad business. An article on this subject in this issue will be found of special interest at this time, as it points out the tendency of events in railway operation, and shows the great strides that have been made in late years in his direction.

Much enthusiasm is being manifested in these meetings on account of the matters of importance that are now before the superintendents for attention and solution.

Mr. P. W. Drew, superintendent of telegraph of the Milwaukee, St. Paul & Sault Ste. Marie Railway, Chicago, Ill., is the secretary of the association and will be glad to give any further information regarding the association and the meetings.

Entertainment for Railway Telegraph Superintendents.

A meeting of the entertainment committee of the Association of Railway Telegraph Superintendents was held on March 12 in the office of Mr. L. S. Wells, superintendent of telegraph, Long Island Railroad, Pennsylvania Station, New York, to consider matters in connection with the annual meeting in New York in June. Mr. L. B. Foley, superintendent of telegraph, Lackawanna Railroad, New York, presided.

It was decided that the convention be held at some other place than at the hotel which the members will make their headquarters. The selection of the hotel and the date of the meeting are to be determined at the joint meeting of the Eastern and Western Divisions of the association to be held in Chicago March 20. It is thought, however, that June 4 will be the date selected for the convention, and it was definitely settled that a banquet should be held at the Waldorf-Astoria on Friday evening of the same week, June 7.

A tentative programme of entertainment was presented by the Railway Telegraph and Telephone Appliance Association. It provides for shopping parties for the visiting ladies; trip through Central Park; visits to museums and other places of general interest; automobile sight-seeing rides, also for the ladies; a visit to the Edison works at Orange, N. J.; theatre or roof garden party; inspection of large ocean steamers in port, for the general party and a visit to the Cortland Street telephone exchange, and the Western Union headquarters. The excursion to the Edison works will take place on Friday, and in the evening, the banquet.

Several prominent old-time telegraphers will be present at the banquet, including Mr. Thomas A. Edison, Mr. W. C. Brown, president of the New York Central Lines, New York, and others. It is expected that between 250 and 300 persons—active and associate members with their families—will be in attendance at the general meeting.

Those present at the meeting, besides Mr. Foley, were the following superintendents and others: G. A. Cellar, Pennsylvania Lines, west of Pittsburg;

Digitized by Google

J. C. Johnson, Pennsylvania Lines, Philadelphia, Pa.; L. S. Wells, Long Island Railroad, New York; E. P. Griffith, Erie Railroad, New York; E. E. Hudson, T. A. Edison, Inc., Orange, N. J.; A. P. Eckert, National India Rubber Company, New York; R. A. Patterson, Duplex Metals Company, New York; W. F. Crowell and A. D. Walters, New York Telephone Company, New York, and T. R. Taltavall, TELEGRAPH AND TELEPHONE AGE, New York.

Telephone Train Dispatching.

The United States Electric Company, New York and Chicago, has delivered since the first of the present month seventy-eight Gill selector local battery bell telephone train dispatching outfits to the Norfolk & Western Railway, together with the necessary sending keys. The Norfolk & Western had, heretofore, 175 of the Gill bridging selector outfits in use and the satisfactory service rendered has led to the extension of the system.

The Baltimore & Ohio Railroad, which has had in service about 150 of the Gill outfits, has received from the United States Electric Company forty-one additional Gill selector local battery bell train dispatching outfits and thirty-five local battery bell intercommunicating telephone selector outfits. An interesting feature of this message circuit is that the United States Electric Company's universal calling key will be used in the intercalling service.

The Turner Monument Fund.

A meeting of the Turner Monument Fund Committee will be held in a few days to fix a date for the dedication of the monument to be erected at Harriman (Turner), N. Y., to commemorate the sending of the first train order by telegraph.

The fund now amounts to $2,325.09, and contributions continue to come in. Anyone who is not financially represented in this worthy movement has yet an opportunity to become identified with it. Remittances should be sent to Mr. J. B. Taltavall, 253 Broadway, New York, who is the treasurer of the fund.

The granite monument is now in place at Harriman ready to receive the bronze tablet, and the work is so far advanced that everything will be in readiness for the dedicatory exercises at the time appointed.

The tablet for the monument is now on exhibition in the window of the Gorham Manufacturing Company's store in Maiden Lane, near Broadway, New York.

The fund now stands as follows: Previously acknowledged, $2,320.09; Charles A. Tinker, Brooklyn, N. Y., $5.00. Total, $2,325.09.

Independent Telephone Convention.

The National Independent Telephone Association held its fifteenth annual convention at the Hotel Sherman, Chicago, on February 7, 8 and 9. President Manford Savage's address was on "The Outlook." "The men who are providing telephone competition," he said, "should not fear government control, investigation or wise legislation. They should favor the enactment of sound public utility laws in each State." He said that the important feature of the year was the fact that the American Telephone & Telegraph Company had abandoned its policy of cutting off independent toll-line connections by the purchase of plants.

Mr. J. C. Crowley of Superior, Wis., spoke on "Experiences under Commission Control," and Mr. S. E. Ward of Mansfield, Ohio, reviewed the telephone situation in Ohio.

Other subjects considered were the life of dry batteries on local-battery telephone lines, pole preservation, distinguishing party-line calls, one-way or kitchen telephone service, use of automobiles in telephone service, and phantom circuits.

A banquet was held on the evening of February 8. The officers will be elected by the board of directors.

Obituary.

John Eagan of the Canadian Pacific Railway Telegraph, Winnipeg, Man., died on February 17, at the age of 66 years.

James Bartlett, aged sixty-five years, a well-known real estate dealer in Amsterdam, N. Y., and formerly manager of the Western Union Telegraph office at that place, died there on February 23.

Mr. H. Campbell, aged 41 years, broker-operator employed by Harriman & Co., New York, died of heart disease on February 29. He was a West Virginian by birth. He worked in Pittsburgh before coming to New York eight years ago.

H. H. Matlock, aged 71 years, a prominent old-time telegrapher in the West, and a member of the United States Military Corps during the Civil War, died at Springfield, Ill., April 6. He entered the telephone service in the early days and installed exchanges in various Iowa cities. Later, he became identified with the Central Union Telephone Company as superintendent for the states of Iowa and Illinois, with headquarters at Springfield. In 1886, Mr. Matlock was sent to Australia by the Western Electric Company to dispose of the telephone property in Victoria to the government, and returned to the United States in the following year.

George F. Macdonald, aged 66 years, an old-time telegrapher and superintendent of fire alarm telegraph, Ottawa, Ont., was found dead in bed, on March 2. He was one of the best-known officials of that city, and was well-known to the members of the Old-Time Telegraphers Association and the International Association of Municipal Electricians, being a regular attendant at their annual reunions. Mr. Macdonald was a man of extreme good nature, and was a popular figure at these gatherings. He had an inexhaustible fund of humorous anecdotes, and kept everyone around him in constant good humor. The members of these two associations, as well as his many friends individually will regret to learn of his sudden death.

Decision on Patent Restrictions.—The United States Supreme Court in a decision on March 11, upheld the right of holders of patents to make license restrictions as to the way the articles they they sell may be used.

UNITED TELEPHONE COMPANY

OUR HIGH POWER TRAIN DESPATCHING SETS

Having the operative parts supported upon an adjustable arm, replace the unsatisfactory and dangerous "Head Receivers" and eliminate induction noises and dangers of lightning discharge.

Provided with a non-metallic megaphone, the volume of tone is greatly increased, distinct enunciation secured, and the effort of constant listening released.

Controlling the main line and local circuits by a semi-automatic switch, operated by the foot, the operator's hands are free for other work and battery waste is prevented.

This apparatus is provided with a transmitter of the power required for the service.

THE MOST SUCCESSFUL ELEMENTARY WORK.

A B C OF ELECTRICITY

By WM. H. MEADOWCROFT

One volume, 12mo. cloth, 50 cents. Fully Illustrated.

This excellent primary book has taken the first place in elementary scientific works. It has received the endorsement of Thos. A. Edison. It is for every person desiring a knowledge of electricity, and is written in simple style, so that a child can understand the work. It is what its title implies, the first flight of steps in electricity.

ENTHUSIASTICALLY ENDORSED BY THE PRESS.

Railroad Telephone Equipment.

Within a period of less than five years a gradual, but none the less decided and revolutionary change has been made in the making in the method of transmitting intelligence over railroad systems. The

FIG. 1—DISPATCHER'S OFFICE.

railroads which interlace the United States are one by one abandoning the use of the time-honored telegraph for this purpose, and are replacing it with telephone equipment, so that at present eighty-seven steam roads are employing the telephone method of handling their train movements over an aggregate of some 60,000 miles of line.

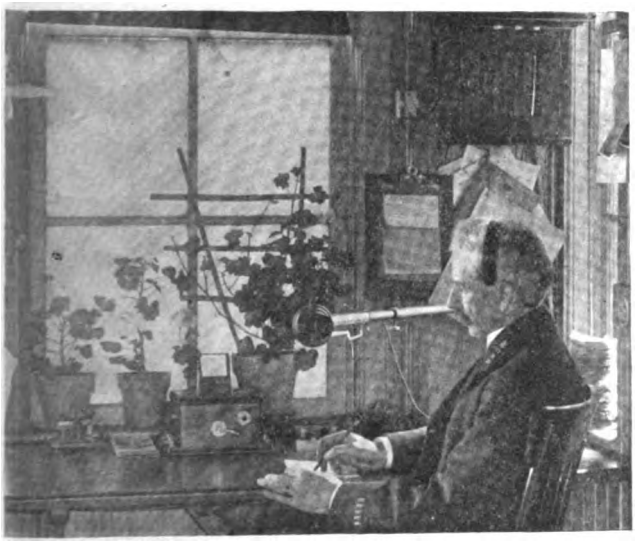

FIG. 2—WAY STATION.

The many advantages accruing from the use of the telephone instead of the telegraph for the dispatching of trains, alone were responsible for its adoption. The telephone, in the first place, is quicker. It has been observed that the ring of the bell will insure a prompt answer, and for this purpose, large extension bells are used, which can be heard several hundred feet away. In the four years that the telephone has been used for dispatching, not a railroad accident has, it is stated, been charged against it, so that it may be said to be as safe as, if not safer, than the telegraph. Furthermore, it has been made possible to increase the length of a division handled by one dispatcher by as much as fifty per cent.

The personal relationship factor, which is always a thing to be desired, is strengthened by the direct personal communication by word of mouth between the dispatcher and the men under him. Discipline is improved and efficiency increased through the agency of the telephone.

It is not intended in this article, to dwell, to any extent, on the operation of the circuits, but, a general statement regarding the working of the new system will not be amiss. The dispatching circuit consists of two wires, and to these are connected the various telephone sets and selectors located at the way stations. When it is desired to call a sta-

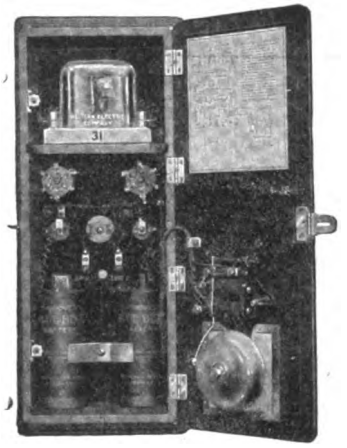

FIG. 3— SELECTOR SET FOR WAY STATIONS.

tion, the dispatcher turns a selector key, which, as the name implies, selects only that particular station desired, and through the medium of the receiving selector apparatus, rings a bell. When two or more stations are wanted on the line at the same time, the proper number of keys are turned by the dispatcher. Train orders are then communicated verbally by the dispatcher, who writes down the order as he delivers it, in order that it may not be delivered faster than the operators can transcribe it. The message is then repeated back to the dispatcher. All proper names and figures are spelled out, as prescribed by the rules of the railroad telegraph associations.

A further feature is, that the telephone circuits are so arranged that the superintendent chief dispatcher, or other road official, can listen in on the line at any time he may desire and inspect the service being given. Such listening-in or observing-service sets can be connected to the circuit at any point.

Perhaps the greatest advantage in the employment of the railroad telephone is in its use in siding and portable telephone sets. The former may be placed at any interval along the right-of-way, or at stated points, such as long sidings, water tanks and drawbridges. In case of emergency they are

Digitized by Google

of infinite value, as they permit the train crew to get into touch immediately with headquarters and get new orders. Another type of apparatus which is also valuable in emergencies is the portable telephone set, which is carried on trains and can be connected or hooked on to the overhead circuit by means of jointed line poles, at any point on the line.

The communications described, are carried over what is known as "train wires," that is to say, wires

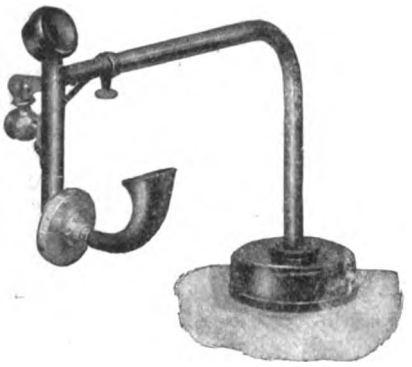

FIG. 4—TRANSMITTER ARM.

which are used only for handling train orders. There are, however, two other classes of wires which will show that the telephone serves other purposes, and facilitates the general transaction of railroad matters.

The "block wire" is a circuit extending from block tower to block tower, and is of use in permitting the tower men to get into easy and quick communication with each other.

The "message wire" is a circuit over which the railroad transacts its commercial and executive affairs. In fact, when used in connection with a private branch switchboard, the railroad has its own telephone system.

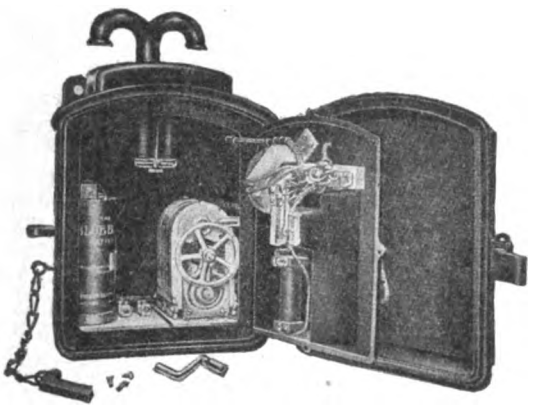

FIG. 5—TELEPHONE SET FOR SIDINGS.

It may not be amiss to mention the "phantom" circuit, which is, in its simplest form, the use of two physical metallic circuits (that is, actual wires), connectd in such a way with suitable apparatus, that, for purposes of transmission, there are three distinct circuits, two physical and one "phantom." It will be seen, readily, that an arrangement of this character effects a saving in wire.

Another circuit, in use where stations are far apart, and where it would be an undertaking involving considerable expense to construct new telephone lines, is the "composite" circuit. This simply means, that telegraph and telephone messages may be sent over the same wire, and, at the same time, by adding certain apparatus and changing the line connections somewhat. A comparatively recent achievement, which is of great value in railroad work, has been the compositing of phantom circuits.

The telephone lines which have been, and are being installed, are built very substantially, and consist, in the main, of two copper wires weighing 210 pounds to the mile. The lines range in length from thirty to 400 miles, and practically any desired number of stations can be installed.

It has been mentioned that eighty-seven railroads have adopted the telephone for train dispatching, and, that these make use of the selective method, employing, in all, approximately 11,500 selectors at the various way-stations. There are, however, a large number of roads not having a length of over thirty miles, which use the magneto telephone, with code ringing, for handling trains. When these are added to the others, the aggregate is, indeed, very large.

A number of roads have their total mileage completely covered by telephone circuits for dispatching trains, and others are attaining this desirable end as quickly as the necessary appropriations are made. It may also be stated here, that the nine-hour law, which was established for telegraph operators, was a factor in getting the railroads to consider the telephone for dispatching work, inasmuch, as the number of extra telegraphers made necessary by the adoption of the new legislation. was not available. The consensus of opinion among railroad men is, that within ten years, the telegraph will have been superseded by the telephone for the more efficient dispatching of all railroad business—train dispatching and commercial.

The telephone sets used in the dispatching equipments are of various types. In many cases, the standard Western Electric desk stands and transmitter arms, equipped with highly efficient transmission instruments, are used. A recent development, by the Western Electric Company, is a loud-speaking receiver. Tests made under the most severe conditions, it is stated, show the articulation to be distinct and the tone of sufficient volume, to make it easy for the operator to hear clearly, no matter how much noise there may be.

Frequently, special transmitter arms have been designed to meet the special requirements of railroad service. One of the most striking of these is arranged so that when the arm is swung into position before the operator, he needs merely to place his head in position to talk. The transmitter and receiver are on a short, adjustable arm affixed to the transmitter arm proper. This does away with the use of a head receiver, and is designed especially for tower service, or that the operator may reach his switches without delay. These arms, which are also of Western Electric manufacture, have been used very successfully wherever installed.

Efficient Primary Battery Cells.

Until within comparatively recent years, many people disliked to use the telephone, the indistinctness of the transmission rendering conversation difficult in a great many cases. Fortunately, these conditions no longer exist for most of us, the rapid strides made by the telephone engineers and manufacturers having brought the modern city system to a point where it is a pleasure to use the telephone instead of a severe strain on the vocal cords as formerly. Metallic circuits, improved instruments and the adoption of the common battery system are mainly responsible for the improvement, a large measure of the credit belonging to the latter, for the reason that it furnishes one of the prime requisites for perfect transmission, viz: steady current.

The importance of an absolutely uniform current for the talking circuit is universally recognized by telephone men, owing to the fact that no change should take place in the secondary circuit other than that brought about by the disturbance in the magnetic field, caused by the vibration of the diaphragm. It is clear, therefore, that good transmission cannot be had when the transmitter circuit is supplied from a battery that rapidly polarizes under discharge, thereby changing the strength of the magnetic field, and seriously affecting the transmission.

The efficient and clear transmission possible with an up-to-date telephone plant can be duplicated in the railroad telephone dispatching systems, by use on the talking circuit, of a battery capable of furnishing uniform voltage with no appreciable increase in internal resistance, as the process of discharge advances, thus establishing the valuable feature of constant resistance in the talking circuit, and eliminating the disturbances incidental to a cell that quickly polarizes and weakens the magnetic field.

It is claimed that the Edison cell fills these requirements so closely that one would think it had been designed for the service. The change in voltage of the 400 ampere-hour cells, when discharged constantly at the rate of .25 amperes, about the average current taken by a transmitter, is a drop of only .07 volts, from the beginning of discharge until the cell is exhausted, indicating that the increase in internal resistance is negligible.

The fact that these cells are so well adapted for transmitter service, however, is not the only feature worthy of attention. It is suggested that the economy which can be effected by their use on account of the long life, ease of renewal and small amount of attention required are characteristics that should receive favorable consideration, even if the battery were no better fitted for the work than the open circuit types. An idea of the saving that can be made in both labor and material can be gathered from the fact that when a set of open circuit cells will operate a circuit one month, a set of Edison 400 ampere-hour cells will, according to the manufacturer, Thomas A. Edison, Inc., Orange, N. J., usually last twenty months. The average annual consumption of a way station transmitter is frequently estimated to be about fifty ampere-hours, and under these conditions the Edison 400 ampere-hour cells will last approximately eight years. Here again is another advantage of the Edison cell, i. e.: the ampere-hour capacity is consumed only in supplying current to the circuit and no energy is wasted due to local action, cells drying out or defects of this nature common to many types of primary cells.

Improved Telephone Train Dispatching Apparatus.

The United Telephone Company, Boston, Mass., calls attention to its high-power train-dispatching telephone sets. The operative parts are supported on an adjustable arm, thus replacing the ordinary head receiver. Induction noises and dangers from injury from lightning discharges are eliminated by this arrangement.

The sets are provided with a non-metallic megaphone, which gives a large increase in volume of tone, and a distinct enunciation is thus secured. One of the advantages in the use of this device, is the doing away with constant listening.

The main line and local circuits are controlled by a semi-automatic switch operated by the foot, thus freeing the hands of the operator for other work; also preventing waste of battery, as it is drawn on only when needed. The apparatus is provided with a transmitter of the power required for the service.

The high-power transmitters, it is claimed, have double the transmitting power of ordinary instruments under the same conditions, or, in other words, they halve the cost of wire now required with present transmitters. They are, moreover, advantageously applicable to the common battery system and where copper circuits are not available provide perfect transmission over iron telegraph wires.

The United Telephone Company also manufactures telephone repeaters that are especially adapted to long distance telephony. They automatically re-transmit speech from one circuit into another without loss of volume or distortion of the articulation. Like the telegraph repeater in telegraphy, they make possible transmission to any distance.

Telephone Train Dispatching in 1911.

(Continued from page 156, March 1.)

Mr. C. A. Parker, superintendent of telegraph of the Denver, Northwestern & Pacific Railway, Denver, Col., writes: "We have not made any progress in developing our telephone or telegraph systems during 1911, as we have done no new building. We have moved our general offices to the new Tramway Building at Fourteenth and Arapahoe Streets, where we have a new private branch exchange board of the latest style, with twenty-four branches and eight trunk lines in use. We hope to extend our line, and string a new telephone circuit this year."

Digitized by Google

Report of Bell Telephone Company of Pennsylvania.

The annual report of Mr. F. H. Bethell, president of The Bell Telephone Company of Pennsylvania, and its Associated Companies, for the year ended December 31, 1911, shows the following earnings and expenses:

EARNINGS.		
Exchange Revenue	$16,123,586.74	
Toll Revenue	3,705,858.04	
Dividends and Interest	32,549.63	
Miscellaneous	388.02	
		$19,862,382.43
EXPENSES		
General Expenses and Taxes	$1,305,957.21	
Procuring and Handling Traffic	5,629,428.32	
Maintenance and Replacements	7,134,621.48	
Instrument Rental ..	863,514.30	
		14,933,521.31
Earnings over Operating Expenses ..		$4,928,861.12
Interest		235,973.46
Revenue Balance		$4,692,887.66
Dividends Declared		3,600,046.00
Balance to Surplus		$1,092,841.66
Surplus, January 1, 1911		4,579,425.86
Surplus, December 31, 1911		$5,672,267.52

The system consists of The Bell Telephone Company of Pennsylvania, The Central District & Printing Telegraph Company, The Chesapeake & Potomac Telephone Company, and the Diamond State Telephone Company and their subsidiary companies.

Radio-Telegraphy.

Signor Guglielmo Marconi and Mr. Godfrey C. Isaacs, managing director of the Marconi Wireless Telegraph Company, London, arrived in New York on the steamer *Lusitania* on March 14.

Senator Marconi.—Signor Guglielmo Marconi it is stated, will be created an Italian senator this month.

Jack Binns Club.—Young wireless amateurs in Cincinnati, Ohio, have organized the "Jack Binns Club," which is to be a clearing house of wireless ideas.

United Wireless System on Steamers.—United Wireless telegraph equipment is to be installed on four steamers of the Insular Line running out of New York.

Change Names of Wireless Stations.—The Navy Department has changed the names of four of its large wireless stations as follows: Cape Elizabeth to Portland, Me.; Point Loma to San Diego, Cal.; Table Bluff to Eureka, Cal., and Unalaska to Dutch Harbor.

Wireless from Chicago to San Francisco.—Wireless messages were exchanged between Chicago and San Francisco, Cal., on March 1, according to a report from the first named city.

Long Distance Wireless.—It is stated that a test wireless message was received recently at Hillcrest station in San Francisco, Cal., from the Arlington station at Washington, D. C.

Wireless Station at Rome.—The Marconi Wireless Telegraph Company has arranged with the Italian government to erect a high-power wireless station at Rome. Two towers will be 240 feet high, and four, 150 feet each.

Wireless on New Torpedo Boats.—The two new submarine torpedo boats, E1 and E2, of the United States Navy, now being equipped at the Newport, R. I., naval station, are the first boats of this type in the United States Navy to be fitted out with wireless apparatus.

Wireless Station at Wellington.—A high power wireless telegraph station is being erected on a mountain peak near Wellington, New Zealand, 1,000 feet above sea level. Two wooden masts, 150 feet high, of the ladder type, will be erected. This station will be able to communicate with Sydney, Australia, and Fiji.

"Radiograms" Official Designation.—The Navy Department, Washington, D. C., on March 1 adopted the word "Radiogram" to designate a wireless message. Attention has been called to the fact that the words "Radiogram" and "Radiograph" have long been used in connection with X-Ray work.

Government Rate for Wireless Messages.—Postmaster-general Hitchcock has fixed fifteen cents as the maximum rate per word that the United States government may pay for wireless messages within the limits of the United States. No charge shall be made for the date and name of place from which the message is sent.

English Imperial Wireless System.—The Postmaster-general of Great Britain has accepted the terms of the Marconi Wireless Telegraph Company for the construction of all the high-power wireless stations required for the imperial wireless system. The Marconi Company will operate the stations for the government for the first six months and then turn them over to the government.

Wireless Suits.—The National Electric Signaling Company has entered suit in the United States District Court, New York, against the Marconi Wireless Telegraph Company of America for an alleged infringement on its patent for the substitution of horizontal transmitting and receiving wires for the vertical wires. The Marconi Company has a counter-suit for the use by the National Electric Signaling Company of a certain tuning patent, for which the latter claims prior rights.

To Regulate Wireless.—A bill was introduced in the United States Senate by Senator Smith, of

Digitized by Google

Michigan, on March 4, to regulate radio-telegraphic communication. It provides for a license to be issued by the Interstate Commerce Commission to all operators of wireless instruments and gives the commission power to regulate the wave length of stations. It is provided that signals from vessels in distress shall be free from interference.

Regulating Clocks by Wireless.—It is proposed to regulate all public clocks in Germany by the aid of wireless telegraphy. An electrician by the name of Ferdinand Schneider has invented a method of accomplishing this result and has received the recognition and support of the German military and naval authorities. A central station is to be erected at Fulda from which wireless waves will be transmitted from a 325-foot tower at one-minute intervals.

Private Wireless Plant in Canada.—In our issue for February 16, reference was made to the wireless telegraph system of the Goodyear Tire & Rubber Company of Canada, between its offices in Toronto and factory at Bowmanville. The distance between the two stations is forty-three miles, and, Mr. F. Barton, the company's wireless operator at Toronto, informs us that the system works very satisfactorily. The equipment used is that of the Clark Wireless Telegraph & Telephone Company of Detroit, Mich.

Wireless Charges in Uruguay.—The central office and branches of the national telegraph throughout the Republic of Uruguay are now transacting business through the radio-telegraph stations charging for the land service (including address and signature) twenty-five centesimos (twenty-six cents) for the first ten words, and two centesimos for each additional word; the radio-telegraph charge is ten centesimos for each word, with a minimum of ten words. The call signal is U M V. All private stations have been closed.

Naval Wireless Regulations.—The Navy Department at Washington has issued orders that alertness on the part of operators at United States naval wireless stations must be maintained during all hours of the day and night. When within range of a naval wireless shore station, vessels of the navy are required to report their position, course and speed. In case it is desired to find a vessel, reference is made to her last position report and her course traced until she is reached through the nearest shore station. The order designates "XXX" as an interference signal, and also "min" for "wait a minute"—denoting interference with business on hand. A ship shall not call longer than fifteen minutes at a time.

Proposals Invited. — Bids are invited by the Bureau of Supplies and Accounts, Navy Department, Washington, D. C., until April 2, for a quantity of magnet wire (schedule 4400), to be furnished at the Boston Navy Yard. Blanks will be furnished by the navy pay office, Boston, Mass., or by the Bureau at Washington.

Franchises in Alabama.—The Supreme Court of Alabama has decided that when a franchise is granted by a city and acted upon by the grantee, that such grant is perpetual unless there are expressed limitations in the franchise. The American Telephone & Telegraph Company was granted a franchise some years ago by the City of New Decatur, Ala., and established a plant and service in accordance therewith. The franchise was later revoked, the city contending that all public service franchises were revokable. The case was carried through the state and federal courts with the result mentioned.

Bunnell Election.—At the annual meeting of the J. H. Bunnell & Co., New York, on March 11, M. J. J. Ghegan was re-elected president and secretary and Mr. C. E. Graham vice-president and treasurer.

Gold and Stock Life Insurance Association.—The printed proceedings of the thirty-fourth annual meeting of the Gold and Stock Life Insurance Association, New York, have been distributed to the members. The pamphlet includes a copy of the constitution and by-laws and list of members. It is neatly gotten up and should be carefully read by the members. Mr. W. J. Dealy, 195 Broadway, New York, is the secretary.

T. M. B. A. Assessment.—Assessment 535 has been levied by the Telegraphers' Mutual Benefit Association to meet the claims arising from the deaths of Michael S. Malony, at New Orleans, La., Edward H. Wade, at Lackawanna, N. Y., Ralph E. Lawrence, at Crafton, Pa., George M. Huntington, at New York, and Jeremiah M. Delaney, at Fort Edward, N. Y.

Investing in California Property.—An interesting proposition is presented to telegraphers by Mr. R. K. Holahan, a well-known telegrapher of Los Angeles, Cal. Mr. Holahan is president of the Telegraphers' California Land Purchasing Agency in that city, and he offers to purchase for telegraphers lemon or orange groves, acreage or lots in and near Los Angeles, and take care of them until such time as the purchaser is ready to occupy the property and take possession personally. This is an excellent opportunity to invest in property that is rapidly growing in value. Further details of this proposition will be found in Mr. Holahan's advertisement on another page in this issue.

Chicago Telegraphers' Aid Society.

At the annual meeting of the Chicago Telegraphers' Aid Society held on February 4, Richard S. Gill was elected president; John J. Harrington, vice-president; Chas. H. Shell, Sr., treasurer, and Alfred J. Fuller, secretary. The reports of the secretary and treasurer show the society to be in a prosperous condition, and, the past year was one of the most successful in the history of the organization.

Digitized by Google

The society is the result of co-operation between 1,000 morally responsible members, to secure insurance during sickness and at death, at the lowest practicable cost, and it is governed by its own members. It was organized in 1889, and has paid $60,000 to members for sick benefits, and $8,400 to members' families as death benefits.

Consolidation of Typewriter Interests. — On March 1, the sales organizations of the Remington, Smith-Premier and Monarch typewriter companies were consolidated. The executive staff of the greater organization will consist of the active leaders of the three original companies. The consolidation is stated to be the first step of expansion for a more aggressive campaign, and many new branch offices will be opened in the United States. Last year's business of the three companies named, it is stated, surpassed every previous record.

LETTERS FROM OUR AGENTS.

CHICAGO WESTERN UNION.

Messrs. H. M. Buckley, assistant chief, and J. D. King, traffic chief, of the Sioux City, Iowa, office, were recent Chicago visitors.

PHILADELPHIA WESTERN UNION.

Mr. I. D. Maize, the well-known veteran telegrapher of this office, celebrated his seventieth birthday on February 28. He received the congratulations of a host of friends at his home, surrounded by his wife, four daughters, two sons and five grandchildren. Mr. Maize is still hale and hearty.

The "Dot and Dash Club" was organized in this city on March 11, in the office of Mr. C. E. Bagley, superintendent of the Postal Telegraph-Cable Company. The following persons were present: C. E. Bagley, A. S. Weir, J. A. Chapman, R. C. Murray, R. C. Mecready, Harvey S. Williams, J. H. Wilson, A. G. Strickland, C. B. Wood, I. D. Maize, L. W. Miller, W. V. Madden and M. N. Redding. The club was organized by the election of Mr. S. S. Garwood, president, A. S. Weir, vice-president, C. B. Wood, secretary, and J. H. Wilson, treasurer. A constitution was adopted and by-laws will be submitted later. Over fifty members were elected. Another meeting will be held on March 25. The object of the club is to promote a more fraternal feeling among the telegraphers, and to hold several dinners during the year at which prominent speakers will be invited to be present. All persons who are or have been at any time Morse operators are eligible, and the membership will probably be limited to 150 to 200.

PHILADELPHIA POSTAL.

The sympathy of the entire office was extended to manager J. A. McNichol on the death, on March 9, of his mother. The funeral on Wednesday, March 13, was attended by many of Mr. McNichol's friends from the office.

Vice-president and general manager E. J. Nally, vice-president C. C. Adams, general superintendent, E. B. Pillsbury and superintendent of messengers, Mr. E. P. Tully of New York, recently paid this office a visit.

Chief operator E. W. Miller went to New York recently on company business.

Wire chief E. P. McElroy has recovered most all of his silver and jewelry which was stolen shortly after Christmas.

Life Insurance is based upon the certainty of death at some time and its possibility at any time. The splendid financial position of the Telegraphers' Mutual Benefit Association, 195 Broadway, New York, is shown in the Reserve Fund of $328,000, which, apart from current assets, amounts to nearly 6½% of the total contingent mortuary liabilities, and yields an annual revenue of more than $15,000. Operating on sound and correct principles, with ample security, it offers to the telegraph and telephone employe the best and most economical form of protection for the family and dependents yet devised. Write for particulars.

WHAT
Western-Electric
SERVICE MEANS To the RAILROADS

TELEPHONE EQUIPMENT of established and reliable quality. Our customers benefit by our more than 30 years' experience as the manufacturer of "Bell" telephone equipment. Western Electric high efficiency transmission circuit is the only "answer" for railroad telephone lines.

SELECTOR EQUIPMENT that is simple and dependable—entire satisfaction wherever installed.

OTHER APPARATUS—including testing and patching panels, repeating and retardation coils, special switching devices—in fact, a Western Electric "answer" to every problem.

LINE MATERIAL, TOOLS AND SUPPLIES furnished by the Western Electric Company—the best of their kind.

COMPLETE STOCKS at our various distributing houses at our customers' disposal. May they never need an emergency shipment; when they do—they will find us ready.

PRICES as low as is consistent with high quality. The price is forgotten but the quality remains as a tribute to our mutual good judgment.

ENGINEERING SERVICES at the railroads' disposal.

CIRCULARS OR CATALOGUE SENT ON REQUEST.

TELEGRAPHERS OF TO-DAY.

"Telegraphers of To-Day," illustrating the personnel of the telegraphic profession as it existed in 1894, with more than 900 biographical and historical sketches of leading members of the craft, is a unique and valuable publication; it has become standard, being the only work of the kind extant. It contains 354 double-column pages, 7 x 11 inches in size, has gilt edges and is bound in imitation morocco—altogether a handsome volume.

Of this fine publication, becoming more and more valuable as time passes, we have but a few copies left. The original price was $5. In order to readily dispose of these remaining volumes, and place them where they rightfully belong, in the hands of every telegrapher who failed to secure a copy at the higher original price, we have cut the figure to $1 a volume. On receipt of this amount the book will be sent to any address, express charges to be paid by the purchaser. At this low rate, a sum below the cost of binding the book even, no telegrapher who desires to own a copy should fail to obtain one at this time, for this "bargain" price can never be repeated, as the book will soon be out of print. Address J. B. Taltavall, Telegraph and Telephone Age, 253 Broadway, New York.

Any electrical or telegraph book published, for sale by Telegraph and Telephone Age, 253 Broadway, N. Y.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

Gas Engines vs. Electric Motors.

One of the things most noticeable when weighing the merits of plans and projects of a novice in electrical or mechanical engineering is his apparent oversight or ignorance of certain conditions which he may and probably will have to meet after the scheme has been put into practical operation.

The knowledge of possible conditions and governing factors can, of course, only be acquired by experience, or by a thorough reading of the subject from the pen of some authority who points them out and suggests the proper remedies.

For illustration let us take the problem of installing motive power, electric or gas, in a small but growing factory and the question resolves into that of: Which will be the most economical, an electric motor or a gas engine?

In order to show the snags a novice is liable to encounter we will give the actual experience of one who decided in favor of the gas engine.

Being somewhat of a mathematician he figured out closely about what horsepower was required and purchased an engine which apparently would meet the requirements.

For about a year everything went smoothly, but afterward business picked up so rapidly that additional lathes and other machinery were required and then he discovered that he had figured too closely and had not made ample provision for future growth. This was his first oversight. A new and larger engine must be bought, while the old one would bring very little sold as second hand.

Another thing he learned, too late, was that a gas engine consumes about the same amount of fuel when running light as it does with a full load. In his case he did not lose much on the plant in that respect because there was usually a full load.

The point to remember in connection with gas engines, however, is that they are economical and most efficient only when worked at or close to their rated capacity. Hence for plants requiring a practically constant power year in and out gas engines are both economical and, in many cases, best suited.

An electric motor, on the contrary, consumes energy only in proportion to the load carried, hence the cost of energy is less when the load is light. Nor is this the only argument in favor of the electric motor for variable loads. Larger machines may be installed thus providing ample provision for future growth at comparatively little additional expense, while the efficiency of the motor is practically the same under all loads. The result of our friend's experience was that he was finally compelled to substitute an electric motor of proper power for the gas engine at considerable expense, but states that since then he has not only been able to meet unusually large temporary demand for power, but he believes he has saved enough in the long run by the change to pay for his first experiment. This illustration must not be taken as belittling the merits of the gas engine, however. The gas engine is all right in its proper place. The failure in this case was due merely to insufficient knowledge of its limitations.

Another fact worth bearing in mind is that nearly all small apparatus for generating electric energy are practically nothing more than expensive toys.

Amateurs of an inventive turn of mind are constantly trying to utilize batteries of small output in connection with low candle-power lamps for electric light in their homes.

They usually imagine that because a miniature one-candle power lamp may be operated by, say a couple of two-volt batteries in series, that sixteen similar lamps arranged in multiples and bunched together should be the equivalent of one commercial sixteen candle-power lamp, and probably be just as cheap to maintain.

Their mistake lies in the failure on their part to understand that, while a standard sixteen candle-power lamp will operate on about three watts per candle, on account of the great care that is taken in their construction for continuous practical il-

Digitized by Google

lumination, a miniature lamp, as usually made, will consume a great deal more energy per candle and otherwise show less efficiency in nearly every respect. In addition to this waste of energy there is always considerable loss due to consumption of the current in overcoming the comparatively high resistance in the battery and external circuit.

In a regular electric light circuit the ratio of external resistance to that of the lamp is so small that practically all the electric energy supplied is utilized at the lamp.

Furthermore, even were it possible to operate sixteen one-candle-power lamps in multiple with a comparatively few number of cells, as proposed, how long do you suppose the cells would last? Let us figure this out.

The energy in watts consumed in any circuit is equal to the product of the current and the voltage of the battery. A standard sixteen candle-power lamp requires a little over one-half an ampere of current, and in order to bring the volume down to that figure a high voltage (usually 110 volts) and a high resistance lamp are required. It is evident, therefore, that if the voltage is reduced the current must be correspondingly increased to get the same product.

Now if a miniature lamp is so constructed that it requires, say two amperes of current per candle, as they often do, with a battery the electromotive of which is but a few volts, it follows that sixteen lamps in multiple would require thirty-two amperes of current, so that even were it otherwise practicable a standard storage battery of 100 ampere hours' capacity would only last a little over three hours, while the toy sizes of primary batteries, which usually go with one candle-power lamps would be exhausted in a very short time.

The same rule applies to a small electric generator. If it possesses a high electromotive force it cannot furnish a great current. It is, therefore, useless for multiple circuit operation. If another machine of the same size possesses a low voltage, it will furnish a correspondingly greater current, but will be useless for long circuits. The total output, however, will be about the same with either machine, but in a different form.

The reason why two machines of like dimensions may give out different forms of electrical energy is that their armatures, etc., are wound with different gauges of wire.

If wound with fine wire there will be a great many more convolutions in the coils than there would be if larger gauges were used. As each convolution increases the electromotive force the fine wire winding of course creates high voltage. But as fine wire possesses high resistance it is not capable of carrying a great volume of current without overheating, and consequent waste of current.

With coarser wire the same space will be filled with fewer convolutions, hence less voltage, but there will be less internal waste and it will carry a greater volume of current.

Owing to the fact that small machines consume so much of the energy uselessly in the way of overcoming high internal resistance, friction of moving parts, their efficiency is as low as 40 or 50 per cent., against 95 or 98 per cent. in the largest sizes. It may be said, in conclusion, that the efficiency of generators increases as their lineal dimensions are enlarged, other conditions being equal, for the reason that a greater percentage of their total output may be utilized in the external circuit.

New Vocation for Telegraphers.—An operator in a Western city spends his spare moments in hypnotizing people. A surgical operation was performed on a man while under the hypnotic influence of this operator, none of the usual anaesthetics being administered. In fact he sang songs while the surgeon's knife was doing its work.

Mr. J. H. Nichols now a prominent business man of Denver, Col., a former old-time telegrapher, and an active member of the United States Military Telegraph Corps during the Civil War, in renewing his subscription states, "I am in no hurry for 'Old Age,' but for the TELEGRAPH AND TELEPHONE AGE, that's different."

Digitized by Google

Personal.

Mr. H. B. Perham, president of The Order of Railroad Telegraphers, St. Louis, Mo., was a recent New York visitor.

Mr. J. Frank Howell, a former telegrapher, now a New York Broker, accompanied by his wife, is spending his winter vacation in Florida.

Mr. W. E. Harkness of the United States Electric Company, New York, has been in Chicago for the past two weeks on business connected with the company.

Mr. Donald Murray, the inventor of the Murray system of telegraphy, sailed from New York on the steamer *Lapland,* March 23, his destination being London.

Mr. William H. Kernan, formerly superintendent of police and fire alarm telegraphs at Bayonne, N. J., was recently granted patents on improvements in fire and police signal systems.

Mr. J. J. Ghegan, president, and Chas. E. Graham, vice-president of the J. H. Bunnell & Co., New York, have returned from a trip to Jacksonville, and other points in Florida, where they spent a few days.

Mr. James F. Gormley of Canton, Mass., a well-known old-time telegrapher, celebrated his seventy-sixth birthday on March 3. Many of Mr. Gormley's old Boston comrades extended their congratulations in person.

Mr. Frank D. Chase, architect of the Western Electric Company, has opened offices in the Peoples Gas Building, Chicago, for the practice of architecture and industrial engineering, making a specialty of manufacturing plants and mercantile buildings.

Mr. Bertram M. Downs, who recently severed his connection with the Brookfield Glass Company, New York, is now associated with the Hemingray Glass Company, Covington, Ky. Mr. Downs has many friends in the electrical field who will wish him success in his new business relations.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. C. C. Adams, second vice-president, is in Philadelphia on company business.

Mr. C. P. Bruch, third vice-president, returned on March 25 from Pinehurst (Southern Pines), N. C., where he spent several days.

A conference of the general superintendent and superintendents of the Southern Division was held at 253 Broadway, New York, on March 26, 27 and 28. Papers were read on "Efficiency of the Service," by Jesse Hargrave, division superintendent; "Receipts," by W. C. Daviet, district superintendent, and "Expenses," by G. W. Ribble, district superintendent, all of Atlanta, Ga. Those present were: Messrs. George H. Usher, general superintendent; Jesse Hargrave, division superintendent; Geo. W. Ribble, W. C. Daviet, W. C. Lloyd and C. H. Ashburn, superintendents, Atlanta, Ga.; F. W. Conger, division superintendent, Dallas, Tex.; Mr. H. A. Tuttle, president and general manager of the North American Telegraph Company, Minneapolis, Minn., was also present. President C. H. Mackay, vice-president and general manager E. J. Nally and other officials were present, as were also the Eastern Division officials, including E. B. Pillsbury, general superintendent; L. Lemon, division superintendent; E. Kimney and C. F. Leonard, superintendents, New York; superintendents C. A. Richardson, Boston, Mass., C. E. Bagley, Philadelphia, Pa., and H. Scrivens, Pittsburgh, Pa. At the conclusion of the three days' conference the entire party was entertained at supper and the theatre on Thursday evening, March 28.

New equipment for the offices at the national conventions to be held in Baltimore and Chicago during June has been ordered.

Postal Telegraph Club of Atlanta.—The annual banquet of the Postal Telegraph Club of Atlanta, Ga., which was to have been held on March 23, has been postponed until some day in April on account of the absence of the superintendents of the Southern Division who attended the conference in New York on March 26. Mr. L. A. Minor is secretary of the club.

Magnetic Club Spring Dinner.—The spring dinner of the Magnetic Club will be held at Moquin's, on Fulton Street, New York, on April 24. Hon. William A. Prendergast, Comptroller of the City of New York, will be present as the guest of honor, and will address the Club. The proceedings of the twenty-third annual meeting of the Magnetic Club of New York, which was held January 11, have been printed in pamphlet form. The Constitution and by-laws of the club and a list of the officers and members are included.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr. Theo. N. Vail, president of this company and of the American Telephone & Telegraph Company, sailed for Europe on March 30, to be absent about two months.

Mr. G. D. Perry, general manager of the Great North Western Telegraph Company, Toronto, Ont., was a recent executive office visitor.

General superintendent J. C. Nelson and division plant superintendent W. C. Titley, Denver, Col., recently made a trip of inspection through Kansas and Nebraska.

Mr. G. M. Yorke, engineer of this company, New York, who accompanied Mr. Belvidere Brooks, general manager, on his recent trip of inspection through the South, has returned.

Mr. W. N. Fashbaugh, traffic engineer, is in Denver, Col., on company business. He attended the joint meeting of the Eastern and Western

Digitized by Google

Divisions of the Association of Railway Telegraph Superintendents in Chicago on March 20.

Mr. C. H. Murphy, general superintendent of Time Service, New York City, was the host at a dinner given at the Brown Palace Hotel, Denver, on Saturday evening, March 16. The dinner was attended by Mr. J. C. Nelson, general superintendent, Mr. W. McD. Milne, division auditor, Mr. S. E. Leonard, division commercial superintendent, Mr. B. L. Brooks, division traffic superintendent, Mr. C. R. Fisher, district plant superintendent, Mr. E. E. McClintock, district commercial superintendent, and Mr. J. F. Reade, manager, Denver. Mr. Murphy left Sunday evening for the Pacific Coast.

Mr. Norman Ringer has been appointed manager of the Dallas, Tex., office to succeed Mr. W. B. Kendall; Mr. O. L. Turner chief clerk to general superintendent; L. McKisick, Dallas, Tex., has been advanced to the position of district superintendent.

Mr. P. W. Johnson, district commercial manager, Boston, Mass., lectured before the Bangor, Me., Chamber of Commerce, on March 21, on "The Use of the Telephone and Telegraph by Business Men."

The following appointments of managers in the Southern Division are announced by Mr. J. S. Calvert, district superintendent, Richmond, Va.: J. B. Irby at Bennettsville, S. C., vice T. B. Smith; Mr. W. R. Staples, Washington, N. C., vice Mr. G. C. Cauthen, transferred to Norfolk, Va., as assistant to the manager; Mr. O. H. Holly, Aiken, S. C., vice Mr. W. J. Terry, who leaves the service; Mr. J. I. Benson, High Point, N. C., vice Miss Genevieve Moore; Miss C. B. Beall, Ft. Monroe, Va., vice Miss Eva P. Wood.

The regular semi-monthly conference of district commercial managers was held in the office of Mr. J. F. Nathan, district commercial superintendent, New York, on March 22.

Mr. W. B. Kendall, manager of the Dallas, Tex., office of this company, has been appointed special agent for the Gulf Division with headquarters at the same place.

Mr. J. C. McGrew, manager of the Erie, Pa., office has exchanged positions with manager R. O. Walters of the Jamestown, N. Y., office.

Mr. Frank E. Coyle, chief clerk to the general superintendent, New York, is spending a few weeks at Lakewood, N. J., recuperating.

Mr. J. D. Felsenheld, general clerk in the office of Mr. J. F. Nathan, commercial superintendent, New York, has been transferred to the office of general superintendent A. G. Saylor.

The Western Union Telegraph Company has completed the installation of automatic printing equipment on three circuits, at Dallas, Tex.

Heavy Work on a Printer Circuit.

On January 9, 1,035 messages were handled, on the Portland-Seattle printer during eight hours' operation, an average rate of 129 an hour. This was the regular run of business, including day letters, railroad deadheads, etc. Mr. C. A. Cook is printer chief; W. E. Brooks, chief operator; J. A. Paquette, night chief operator; T. A. Long, late night chief at Portland.

Injunction Granted Western Union.—The Western Union Telegraph Company has been granted a temporary injunction restraining the Wisconsin secretary of state from canceling its charter in that state. The litigation grew out of the removal by the Western Union Company of a damage suit from the state to the federal court in violation of a state law.

Western Union Quarterly Report.

The report of the Western Union Telegraph Company for the quarter ending March 31, shows the estimated condition of the company at the close of that period as follows:

Surplus December 31, 1911		$12,291,634.66
The net revenues of the quarter ending March 31, based upon completed returns for January, partial returns for February and estimating the business for March; less quarterly assessment for Repairs and Depreciation pursuant to Executive Committee's resolution of January 31, 1912, conforming to president's annual report of 1911, will be about	$1,220,000.00	
Less interest on bonded debt	434,250.00	
Leaves estimated net earnings for the quarter, less interest on bonded debt.		785,750.00
		$13,077,384.66
It requires for a dividend of three-fourths of one per cent. on capital stock issued about		747,970.00
Deducting which, leaves a surplus, after paying dividend, of		$12,329,414.66

A dividend of three-fourths of one per cent. was declared payable April 15.

Mr. Lewis Cass Ledyard, of New York, was elected a director of the company.

J. C. Willever, United States Manager Western Union Cable System.

Mr. John C. Willever recently appointed United States manager of the Western Union Cable System with headquarters at New York, is a widely known and experienced man in the telegraph service and is eminently fitted to fill the exacting and delicate duties of his new position.

Mr. Willever is a native of New Jersey, having been born at Montana, Warren County, that state, on March 9, 1865. After a short service with the Delaware, Lackawanna & Western Railroad Company and the Central Railroad of New Jersey, he entered the employ of the Western Union Telegraph Company at Asbury Park, N. J.,

Digitized by Google

in 1881, afterwards coming to New York, where he has been continuously identified with the service in various capacities except for a short period of employment as private line operator for the banking firm of John H. Davis & Co. He became private secretary to the late president of the Western Union Telegraph Company, General Thomas T. Eckert, and with the advent of the administration of Col. R. C. Clowry, was appointed chief clerk in the executive offices. On January 1, 1909, he was elected secretary of the company which office he held until recently when it was relinquished in order that he might apply himself to the more active and important work in which he is now engaged.

J. C. WILLEVER, NEW YORK,
United States Manager Western Union Cable System.

Mr. Willever's appointment as United States manager of the company's cable system is a well-merited reward for long and faithful service and a recognition of his particular qualifications for the post.

The Cable.

West India & Panama Telegraph Company.—Shares in the West India & Panama Telegraph Company have advanced considerably lately in the London stock market. The activity of the stock is supposed to be due to the fact that the opening of the Panama Canal will result in increased business.

Divers Cutting Cable.—In a recent number of *The Illustrated Tribune* of Rome, Italy, is given a full page colored print showing divers at work cutting a submarine cable, in connection with the war between Italy and Turkey, under the Red Sea. As the water was shallow the work of the divers was comparatively easy. Cable cutting is one of the necessities of modern warfare between nations.

French Submarine Cable.—A bill has been submitted to the French Chamber for establishing an additional cable between Marseilles and Algiers, and the construction of a new aerial line between Paris and Marseilles for the service of the cable. There are now three cables between France and Algeria (Marseilles-Algiers), laid respectively in 1871, 1879 and 1880, and another between Marseilles and Oran, laid in 1892. In addition there is a cable between Marseilles and Tunis, laid in 1893, and another between Oran and Tangiers, laid in 1901. The proposed new Marseilles-Algiers cable is to be constructed during the winter of 1912-1913 and laid in the spring of next year.

The "All-British" Cable.

At a meeting in London, on March 13, of the Associated Chambers of Commerce of the United Kingdom, the desirability of an "All-British" transatlantic cable was urged. Sir John Barron, M. P., parliamentary secretary to the postmaster general, said that the Post Office had already obtained considerable reductions in rates from the cable companies, and although Great Britain did not own the cables, they all began and ended on British territory, and therefore England virtually had control of them.

If the British Government laid a cable across the Atlantic, he continued, it could only be maintained at a continuous loss. Moreover, great developments were now taking place in wireless telegraphy, and very shortly there would be introduced a machine which would transmit telegrams between England and other parts of the British Empire at a rate of fifty words per minute. At a dinner in the evening Hon. Herbert L. Samuel, postmaster general, stated that the government before long would obtain control over all cable business. This, the despatch states, is understood to have reference to the lapsing of the landing licenses at an early date, which can only be renewed on condition that the government have control of the rates charged.

Municipal Electricians.

Police Telegraph in Beverly.—A police telegraph system is being installed in Beverly, Mass.

Convention of Municipal Electricians.—The executive committee of the International Association of Municipal Electricians will hold a meeting in Peoria, Ill., some time in April to fix a date and make other necessary arrangements for the annual convention of the Association which will be held in Peoria. Mr. Clarence R. George, city electrician, Houston, Tex., is secretary of the association.

Continental Telegraph Company.—The Continental Telegraph Company, which operates on the Chicago, Milwaukee & Puget Sound; the Tacoma Eastern; the Gallatin Valley and White Sulphur Springs and the Yellowstone Park Railways has 172 offices in North and South Dakota, Washington, Montana and Idaho, and many important cities in these states are reached by the lines. There are offices at Seattle and Spokane, Wash. Some unusual names appear in the list. In Montana there are offices at Straw, Two Dot, Sixteen and Three Forks.

The Telephone.

Mr. H. J. Pettengill, president Southwestern Telegraph and Telephone Company, Dallas, Tex., was a recent New York visitor.

Telephone Election.—The annual meeting of the stockholders of the Western Telephone & Telegraph Company, was held in Pittsburgh, Pa., March 19, and all the retiring directors were re-elected.

Cumberland Company Mortgage.—The Cumberland Telephone & Telegraph Company has filed a mortgage for $15,000,000 covering its property in Kentucky, Tennessee, Louisiana, Mississippi, Indiana and Illinois. Mr. W. T. Gentry, Atlanta, Ga., was recently elected president of the company.

Telephone Numbers as Telegram Addresses.—The British Postmaster-General recently announced that hereafter telephone numbers may be used as telegraph addresses. This will save the public the expense which it had formerly to incur in registering their telegraphic addresses.

Telephone Rates in British Columbia.—The British Columbia Telephone Company on April 1 inaugurated new rates in Victoria and Vancouver. The rate for unlimited service for a business house is $5 per month, an increase of $1 per month. The long-distance rate from Vancouver to Victoria is 60 cents per minute.

Examination for Superintendent of Telephone Construction.—The United States Civil Service Commission, Washington, will hold an examination on May 29 of applicants for the position of superintendent of telephone construction in the Forest Service, Department of Agriculture. The salary is $1,500 per year and the age limit 28 to 45 years.

Texas Telephone Lines Purchased.—The The Southwestern Telegraph & Telephone Company has purchased two independent telephone lines in east Texas and the long distance lines of two other companies. The independent lines affected are the Cleveland Telephone Company, the Sabine Valley Telephone Company, the Yellow Pine Telephone Company and the Long View Telephone Company. The lines will be greatly improved and extended.

Government Ownership of Telephones.—A bill has been introduced in the House of Representatives at Washington, to provide for the condemnation, acquisition, and construction by the United States of the telephone lines, properties and holdings in the United States, and to provide for the operation of the same by the United States. The power to determine the market value of the properties thus to be acquired is to be vested in the Interstate Commerce Commission, and that body, the postmaster-general and the commissioner of telephones, an official to be appointed, are to decide which company should be proceeded against first.

Annual Meeting of A. T. & T. Co.—At the annual meeting of the stockholders of the American Telephone & Telegraph Company, held in New York, March 26, Messrs. Charles Francis Adams, 2nd, George P. Gardner and Richard Olney, all of Boston, were elected directors, filling the vacancies caused by the death of Thomas Sanders and the resignations of Thomas B. Bailey and Frank E. Warner. The other directors were re-elected. At the subsequent meeting of the directors the officers were re-elected with one change, Mr. A. A. Marsters being elected secretary in place of Charles Eustis Hubbard, who declined re-election, having held the position of secretary since the organization of the first Bell Company.

Officers of National Independent Telephone Association.—The following officers were elected in Chicago, March 11, by the Board of Directors of the National Independent Telephone Association: President, Mr. Manford Savage, Champaign, Ill.; first vice-president, Mr. E. B. Fisher, Grand Rapids, Mich.; second vice-president, Mr. W. J. Thomas, of Kentucky; secretary, Mr. Richard Valentine, Janesville, Wis.; executive committee, Mr. Savage, Mr. Fisher, Mr. Valentine, Mr. L. D. Kellogg of Chicago, Mr. H. D. Critchfield of Chicago, Mr. Theodore Gary of Macon, Mo., and Mr. N. G. Hunter of Wabash, Ind. President Savage and most of the other officers were re-elected.

Bell Telephone Company of Canada.—At the annual meeting of the Bell Telephone Company of Canada, held in Montreal, recently, Mr. C. F. Sise, President, gave out the figures representing the company's business during the year. Net revenue for 1911 amounted to $1,425,835, out of which was paid $1,000,000 in dividends. About 20,000 new subscribers were added, giving a total number of instruments now earning rental of 153,959. The system now comprises 58,300 miles of wire, of which 4,167 miles were added during the year past.

After deducting from the balance of revenue account the various charges for depreciation, etc., there is left a balance of $120,415 to be carried to 1912.

The retiring board of directors was re-elected as follows: Mr. C. F. Sise, president, the Hon. Robert Mackay, vice-president; Theo. N. Vail, Robert Archer, Wm. R. Driver, Hugh Paton, Charles Cassils, H. B. Thayer, L. B. McFarlane, Z. A. Lash, K.C.

Canadian Notes.

Mr. J. Frank Richardson, superintendent of telegraph, Canadian Pacific Railway, Montreal, Que., was recently presented with a purse of gold by the employes of the Eastern Division of the road, the occasion being Mr. Richardson's transfer to a similar position at Vancouver, B. C.

A Knotty Problem.—An exchange wants to know if when a Postal manager marries a woman railroad telegraph operator in California, it is a Western union tie-up.

Radio-Telegraphy.

Signor Guglielmo Marconi was made a life-member of the Italian Senate on March 4.

Mr. Marconi will be a guest of honor at the dinner of the Associated Press and the American Newspaper Publishers' Association in New York, on April 25.

A dinner was given in honor of Mr. Marconi and his associates by the *New York Times* in New York on the night of March 16 on which occasion congratulatory wireless messages were exchanged between the *Times* office and London, two messages coming from London in ten minutes. This is stated to be record time for wireless communication between the two points.

Mr. Marconi has left New York for Glace Bay, N. S., to inspect the Marconi Wireless station at that point.

Report of American Marconi Company.—The annual report of the Marconi Wireless Telegraph Company of America shows a profit for the year of $16,992.

Improving Wireless Station at San Pedro.—The station of the United Wireless Telegraph Company at East San Pedro, Cal., has been enlarged and otherwise improved to meet with the increasing business.

Wireless Tuition in Paris.—The committee of the International Society of Electricians, Paris, France, has decided to institute at its school a special section for practical and theoretical instruction in wireless telegraphy.

Lecture by Marconi.—Signor G. Marconi will deliver a lecture before the New York Electrical Society, at the Engineering Societies Building, 29 West Thirty-ninth Street, New York, on April 17, on the subject of "Wireless Telegraphy."

Extending Marconi Service.—The Marconi Wireless Telegraph Company of America will increase its capital stock to $10,000,000 and will establish wireless stations at New York and London at once. It will also erect stations at Panama and Cuba and down the east and west coasts of South America.

Wireless Telegraphy Over Desert.—Dr. H. L. Coffman of Palm Springs, Cal., is securing estimates on the cost of installing a series of wireless telegraph stations to cover the upper reaches of the Conchilla desert. The plan is to establish at least five stations.

Wireless News Service to Honolulu.—The first press despatches received by wireless direct from San Francisco were published in the *Hawaiian Gazette*, Honolulu, on February 27. They were received at the Kahuku wireless station and telephoned thence to the newspaper office.

Wireless Telegraph Engineers.—The annual meeting of the Society of Wireless Telegraph Engineers was held at the Hotel Manhattan, New York, on March 4. Officers were elected as follows: President, Mr. F. Lowenstein; vice-president, Dr. Louis Cohen; secretary, Mr. J. L. Hogan, Jr.; treasurer, Mr. E. D. Forbes; managers, Messrs. G. W. Pickard, E. R. Cram and J. S. Stone. The society's headquarters have been moved from Boston to New York. The address of the secretary is National Electric Signaling Company, Bush Terminal, Brooklyn, N. Y.

Marconi Company Absorbs United Wireless.

When the suit of the Marconi Wireless Telegraph Company against the United Wireless Telegraph Company for alleged infringement of patent rights was brought to trial in the United States district court, New York, on March 25, it was announced that in consequence of a settlement being reached between the two corporations the United Company would make no defense, and would consent to the granting of the decree in favor of the Marconi Company. It was later learned that a merger agreement had been consummated between the Marconi and United wireless companies as the result of which the stations and contracts of the United Wireless will pass into the control of the Marconi Company.

The Arlington High-Power Wireless Station.

In response to a request for details of the new high-power wireless station now being erected by the Navy Department at Arlington, Va., near Washington, D. C., Mr. R. S. Griffin, acting chief of the Bureau of Steam Engineering, sends us the following:

This station is to consist of three steel towers. One tower is to be 600 feet high and 150 feet square at the base, and the two smaller towers 450 feet high and 120 feet square at the base. All three are to be of ornamental steel construction. There will be three buildings connected with the station, to be of tapestry brick and in keeping with the ornamental construction of the towers. The first of these buildings will be the house of the officer in charge of the station. The second will be the receiving building, which will contain a sound-proof room for the apparatus, the dormitory for twenty operators, a library, a living room, kitchen, laundry, operator's office, the office of the officer in charge of the station, and a large laboratory for the test of apparatus. The third building will be the transmitter building, which will contain the engine room, a machine shop, a laboratory, and several rooms for a radio museum.

In the engine room will be installed a 200-h.p. motor belted to a 100-kw. generator; a 15-kw. oil engine-driven generating set for charging storage batteries, and various other generators for test purposes. A low-powered set of about 5 kilowatts will probably also be installed, as will a 200-h.p. oil engine set, and storage batteries for the large set in case the other sources of power should fail.

With the high-powered set it is believed there will be communication at all times with ships in the North Atlantic ocean, with a similar station to be erected at Colon, and one to be erected at some place on the Pacific coast.

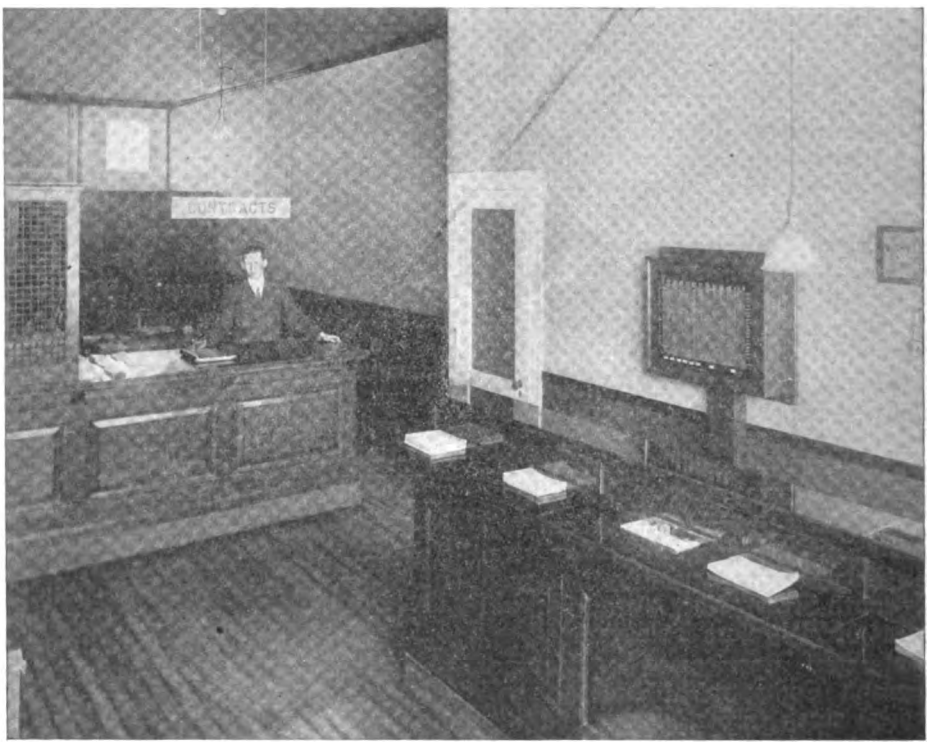
Joint Telegraph and Telephone Office.

The accompanying illustration shows the joint office of the Western Union Telegraph Company and the New York Telephone Company at Hudson, N. Y., as described by Mr. J. J. Malone, manager, in the *Telephone Review*. The office is located in the business centre of the city on the ground floor of a modern three-story brick building and is furnished with up-to-date furniture and equipment.

Since the joint occupancy of the office, business has had a healthy increase as a result of a systematic campaign in educating the patrons of the companies in the advantages of co-operation of the two services.

The desks of the telegraph and the telephone interests are shown in the illustration, and one may gain a general idea how the public room of a modern telegraph-telephone office looks.



INTERIOR OF JOINT TELEPHONE AND TELEGRAPH OFFICE, HUDSON, N. Y., SHOWING ARRANGEMENT OF RESPECTIVE COUNTERS.

Tests for English Telegraph Messengers.

The telegraph boy who sits on a convenient doorstep engrossed in Scott's "Ivanhoe" these days has a reason, or an excuse, for refusing to recognize the urgency of the "wire" packed in his leather pouch, says the *London Standard*. This reason or excuse is that the Civil Service Commissioners have made an essay on the famous novel one of the tests for this year's examination which must be passed by all messengers who wish to get permanent employment in the service. The examination takes place in April. The syllabus has just been issued, and eligible youths now wander through the corridors of the building in King William-street with a far-away look in their eyes conning the story of Rowena the fair.

Handwriting, spelling, and geography are among the other items in which the would-be civil servant must be proficient—but in order to curb the enthusiasm of the candidates it is pointed out coldly that in the handwriting section "all flourishes and superfluous strokes should be avoided." Further, it is stated that "the slope from the vertical should be even and not exceed thirty degrees."

The successful messenger boy must know how to treat vulgar fractions "simply," and understand the principal railway routes and many other matters of geography. He stands in danger of being "plucked" unless he can give a summary of political, industrial, and social England from 1760 to the present day, and he must be able to give the position of the principal countries in the world and their important physical features and towns; the influence of surroundings upon occupations and methods of life and the chief means of international communication by land and water. Yet, in spite of all that and after correct answers have been made, the candidate will be disqualified if he is flatfooted.

It is evident from this that the applications for position as messengers in England must be so numerous that they have to be weeded out by the civil service process. In this country the telegraph companies are not afflicted that way; they have to go gunning for good messenger material.

Annual Report of American Telephone and Telegraph Company.

The annual report of the directors of American Telephone & Telegraph Company to the stockholders for the year ending December 31, 1911, was presented by President Theo. N. Vail, at the annual meeting of the Company on March 26.

At the end of the year the number of stations which constituted the system in the United States was 6,632,625, an increase of 749,906, including 306,403 connecting stations. Of these, 2,158,454 were operated by local, co-operative and rural independent companies or associations having sublicense or connection contracts, so-called connecting companies.

The Bell telephone toll lines of the United States now reach 70,000 places, from many of which a telegraph message can be sent. The extent of the system is best realized by comparison with less than 65,000 post offices, 60,000 railroad stations and regular telegraph offices at about 25,000 places.

The total mileage of wire in use for exchange and toll service was 12,932,615 miles, of which 1,290,403 were added during that year. Of the total mileage nearly 11,000,000 miles were exchange wires, and 2,000,000 toll wires. These figures do not include the mileage of wire operated by connecting companies. Of this total wire mileage 6,831,667 is underground, including 411,406 miles of toll wires in underground cables. The most important development is in the Boston-Washington Subway, now completed with the exception of drawing the cable into the Providence-New Haven section. This subway will be about 450 miles in length, and contain about 2,100 miles of single duct and 79,000 miles of wire in the first cable.

Including the traffic over the long-distance lines, but not including connecting companies, the daily average of toll connections was about 645,000, and of exchange connections about 23,484,000, as against corresponding figures in 1910 of 602,500 and 21,681,500; the total daily average for 1911 reaching 24,129,000, or at the rate of about 7,770,000,000 per year.

The amount added to plant and real estate by all the companies, excluding connecting companies, constituting the company's system in the United States during 1911 was $55,660,738. It is estimated that about $56,000,000 will be required for current additions to plant in 1912, of which amount some $30,000,000 will be provided by the existing and current resources of the company.

During the year $58,840,000 was applied out of revenue to maintenance and reconstruction purposes; of this, over $12,000,000 was unexpended for those purposes.

The total provision for maintenance and reconstruction charged against revenue for the last nine years was over $342,300,000.

Tables show the business for the year of the Bell Telephone system including the American Telephone & Telegraph Company and its associated holding and operating companies in the United States, but not including connecting independent or sub-licensee companies, nor the Western Electric Company and Western Union Telegraph Company except as investments in and dividends from those companies are included respectively in assets and revenue.

The gross revenue collected from the public in 1911 for telephone service by the Bell System—not including the connected independent companies—was $179,500,000; an increase of nearly $14,000,000 over last year. Of this, operation consumed $60,000,000; taxes, $9,000,000 or one and one-half per cent. on the outstanding capital; current maintenance, $30,200,000; and provision for depreciation, $28,700,000.

The surplus available for charges, etc., was $51,600,000, of which $13,600,000 was paid in interest and nearly $26,000,000 was paid in dividends.

The total capitalization, including inter-company items and duplications, of the companies of the Bell System is $1,186,639,036. Of this, $524,679,951 is owned and in the treasury of the companies of the Bell System. The capital stock, bonds and notes payable outstanding in the hands of the public at the close of the year were $662,000,000. If to this be added the current accounts payable $23,400,000, the total outstanding obligations of every kind were $685,400,000, as against which there were liquid assets, cash and current accounts receivable, of $74,800,000, leaving $610,600,000 as the net permanent capital obligations of the whole system outstanding in the hands of the public.

Against these obligations, the companies had actual, tangible property, not including franchises, patents or good will, which cost $754,200,000, an excess of 23 per cent. over the obligations.

For the year there was an increase in assets of $78,600,000, of which $55,600,000 represented current additions to plant, including the necessary real estate. This increase of $78,600,000 is represented by $51,600,000 increase in outstanding obligations for the whole system, and an increase in surplus of $27,000,000. Of this $27,000,000 surplus, about $4,500,000 represents premiums on capital stock received through conversion of bonds.

This surplus, which does not include any of the intangible, though necessary and valuable assets, is invested in productive property not represented by any capital charges, the revenue from which enables the company to maintain its efficiency and at the same time make concessions to the public in the way of gross charges.

A table shows average operating revenue and expenses per station, operating ratios, unit plant costs, etc., of the associated operating companies (not including the American Telephone & Telegraph Company's long-distance lines), for the years 1895, 1900, 1905, 1910 and 1911.

There has been a steady decrease in revenue per subscriber's station, so that now the average subscriber pays for a higher grade, more comprehensive service, less than half what he paid sixteen years ago for much less useful service that was then possible.

Although there has been a decrease in cost of operation every year till 1910, there was an in-

Digitized by Google

crease in 1911 over 1910. This is mostly accounted for by increased operators' wages.

The greatly decreased plant investment per station has been still further reduced during the year to $141, notwithstanding the extensive additions to toll lines and the continued increase in the proportion of wires underground.

The net earnings of the American Telephone & Telegraph Company for the year were $33,301,245.77, an increase of $1,368,031.28 over 1910. The interest charges were $5,567,980.30, and the dividends at the regular rate of 8 per cent. were $22,169,449.79. Of the balance, $5,563,815.68, there was carried to Reserves $2,800,000.00 and to Surplus $2,763,815.68.

No dividend on the stocks of the associated companies was increased during the year excepting the increase from 6 per cent. to 7 per cent. in the rate on the stock of the New England Telephone & Telegraph Company, made in the second quarter of the year.

During 1910 and 1911 over $23,000,000 of capital advances to associated companies were exchanged for stock of those companies. * * * The resulting decrease from this cause in the American Telephone & Telegraph Company's revenue is at the rate of over $825,000 per year, that amount additional remaining in the surplus of companies in which this company has about 95 per cent. interest.

The total outstanding capital stock and bonds of the American Telephone & Telegraph Company at December 31, 1911, were as follows:

Capital Stock	$318,427,500
4 Per Cent. Collateral Trust Bonds	78,000,000
4 Per Cent. Convertible Bonds	20,459,000
Total	$416,886,500

For the $318,427,500 capital stock, $339,633,235 has been paid into the treasury of the company; the $21,205,735 in excess of par value represents premiums. All discounts on the bond issues have been charged off. The outstanding capital obligations therefore represent over $21,200,000 more than their par value.

The Legal Department reports that the relations of the company and its associated companies with the Public Service Commissions of the several states have continued to be of a very satisfactory character. The telephone companies have co-operated with the Commissions in the endeavor to provide the best possible service. There are now Commissions with jurisdiction over telephone companies in twenty-eight states. Some of the decisions of these Commissions are illuminating, and support what we consider to be the soundest policy.

The year 1911 has, as usual, been an active one for the general engineering staff maintained at headquarters for the benefit of the associated companies throughout the United States.

In improving the transmission of speech a most important work has been the development of methods whereby the loading coil invention can be applied to the heaviest gauge wires and whereby such wires, when equipped with loading coils, can be operated on the phantom principle. By this means telephone service is now successfully accomplished between New York and Denver and the transmission of speech between cities less far apart has been greatly improved. By the application of the phantom principle to such circuits the available facilities have been largely increased so that between the important telephone centers notable improvements in service have been accomplished.

In long underground cables improvements have also been made so that the phantom principle may be employed in them, and the range over which speech may be transmitted has been so far increased that when this type of cable is installed between Boston and Washington it will be possible to talk underground between those cities and all of the intermediate points, which would have been impossible under the previous state of the art.

Fundamental plans have been made for the associated companies in twenty cities. These provide for the proper location of subways and central offices so as to insure the most efficient growth of the plant. The construction contemplated in these plans amounts to more than $100,000,000.

In different parts of the country a large number of important central office installations have been planned. When completed, the expenditure based upon these plans will amount to $10,000,000.

Under the rearrangement of territory the American Telephone & Telegraph Company, controlling the entire Bell System, will, as it has in the past, exercise the functions of a "centralized general administration." All questions of policy common to all, all common matters which may have an effect upon the system as a whole, will be settled by the Central Administration. As one administration will do for all what each would have to do for itself, it has the advantage of economy and will maintain uniformity.

For operating purposes there will be eight or ten divisions with boundaries determined by present commercial conditions, instead of a much larger number of divisions with boundaries fixed more or less accidentally or by other considerations prevailing twenty-five or thirty years ago.

All lines of responsibility and suggestion will go up, from the local representatives to the Central Administration. All lines of authority down, from the Central Administration to the local chief.

Under the Bell organization each associated company or group of companies is now, and each division hereafter will become an autonomous whole, with its own local control and identity, and within the limits of the general policy and authority, absolute on matters pertaining to or which affect only that territory.

INDEPENDENT AND OPPOSITION COMPANIES.

We have, says the report, wherever we could do so legally and upon satisfactory terms, and acting with the acquiescence and consent of the local public and local authorities, purchased, merged or made connecting contracts with a large number of independent or opposition companies. Wherever these arrangements have been

Digitized by Google

completed and put into operation there seems to be general satisfaction with the result.

GOVERNMENT OWNERSHIP.

The discussion of the government ownership of the wire companies is not likely to become anything more than academic, at least for the present, continues the report. Even if the final conclusion should favor government purchase of all wire plants, there would be no unfavorable consequences to the shareholders of the wire companies other than the obligatory liquidation. Any possible award for the property which the security holders would be obliged to accept would give them better than current prices for their securities.

It is, however, highly desirable that if there is to be discussion, it should be on the right lines and that whatever be the conclusion it should be reached after a full consideration of conditions as they exist, and of the practical experience of other countries, and not be based upon theories, expectations, prophecies, promises with no power to fulfill, or wrong ideas of existing conditions.

Government operation of the telegraph would necessarily require the ownership, maintenance and operation of the transmission facilities and equipment, as well as the solution of many complex problems incident thereto, including that of profit and loss, all new to our form of government. Hundreds of millions must be invested in purchase or reproduction of facilities, all the charges on which, together with other costs, must be met out of the revenue from the service or become a charge on the general public revenue—all for the benefit of the comparatively few who would directly or indirectly profit by the use of the service.

In the arguments and prophecies that are being used in support of government ownership, history is but repeating itself. The same undervaluation of existing plants, the same exaggeration of the profits, the same optimistic and exaggerated statements of what would be the results of government operation that were made in favor of government ownership in other countries are now being made.

The facts are, that there is hardly a telegraph or telephone system in the world now operated by any government which shows a profit, even under accounting methods employed, and not one that would not show a deficit under accounting methods obligatory upon private enterprise. For authority, see any department report of any government telegraph system.

Another consideration, much misunderstood and often misstated, is the supposed superiority and cheapness of service in other countries.

There is not a single instance of telegraph or telephone companies operated by private corporations in competition with government operation, where the private service is not better than the government and profitable, against unprofitable government operation, if untrammelled by government interference.

TELEPHONE AND TELEGRAPH.

The inter-operations of the telegraph and telephone systems are improving rapidly. The collection and delivery of telegraph messages by telephone is becoming popular. Telegraph facilities have been largely extended, and will soon be much further extended, by agency telegraph offices established at telephone toll stations, and by the connection of the telephone system with telegraph "all-night" offices. All these innovations have been of convenience and advantage, and in case of emergency a great benefit, to the public, but they have not as yet been productive of economy in operation or of profit.

The Western Union system is to the telegraph situation what the Bell System is to the telephone situation, in that each tries to give a comprehensive universal service, but the comparison ends there.

The Western Union has over 25,000 offices in over 21,000 places, and in addition many thousand agency offices at the toll stations of the Bell System. From less than 2,000 of the 21,000 places, with an aggregate population of about 40,000,000, over 90 per cent. of its entire revenue is obtained. Nearly 17,000 of the 21,000 places have an average revenue of but slightly above $10 a month with a maximum of $50 a month. Some joint operating arrangement, generally with the railroad telegraph service, has been made for these and many other places where the revenue is insufficient to maintain an exclusive Western Union office. The increasing demand of the railroad telegraph service upon its operators, and because their first duty is to the railroad service, places the commercial telegraph service in a secondary place, which, with the best of intentions, is not conducive either to promptness or efficiency.

The Bell Telephone System has scattered over the whole territory exchanges or toll line centers from which radiate subscribers' circuits and branch toll line circuits. These centers are connected with each other by toll or long-distance circuits and constitute the telephone system. The toll circuits of the telephone system reach 70,000 places. At most of these places and upon substantially all of these branch toll circuits, and on many circuits connecting into the intermediate stations on trunk lines, there is not enough business to occupy fully either operators or wire facilities; were it not for the indirect advantage to the whole system few, if any, of them would have been established. While the telephone cannot be used interchangeably with the telegraph instruments in the transmission of messages over busy circuits by busy operatives, the "not-busy" operatives and circuits could be used for telephone and telegraph service "alternately" instead of "simultaneously," as there is not enough business to justify such circuits being "composited,"

Digitized by Google

i.e., arranged for simultaneous use of telegraph and telephone. The joint use of such lines and operatives would be a source of economy. At busy offices, and on busy circuits, the circuits could be "composited" for the simultaneous use for telegraph and telephone purposes. Each service would require its distinct operating force and its distinct offices, as the services rendered by the telegraph and the telephone are functionally and fundamentally different although both use wire circuits. The telephone makes up a circuit and places it at the use of the customers, who do the communicating; *i.e.*, it leases its circuits to others for personal communication. The telegraph by its own operators performs all the services of collecting, transmitting and delivering messages; *i.e.*, it transmits over its circuits, for others, personal communications.

The great economy and advantage would come from the "compositing" or simultaneous use of one system of circuits for the two services, eliminating entirely one of the wire systems. The advance in the state of the art of "compositing" lines for joint use of the telephone and telegraph has been very marked in the very recent past.

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. The review of Maver and Davis' book. "The Quadruplex," was completed in our issue for February 16, and the next book to be taken up and treated in like manner is "Electrical Instruments and Testing," by Norman H. Schneider, with chapters on testing wires and cables and locating faults, by Jesse Hargrave, a well-known and capable electrical engineer. These subjects will no doubt prove of great interest to students, as they are timely and important, and each student should have a copy of the book at hand in order to follow intelligently the study of the subjects under consideration.]

GALVANOMETERS (Continued)

What is the diameter of the coil of a tangent galvanometer?

How long is the needle?

What is a tangent?

How are the deflections of the needle compared?

If the needle is deflected five degrees, with a given current, and with another current the deflection is ten degrees, does it mean that the second current is twice as strong as the first?

Why is it necessary to move the galvanometer around so as to bring the needle point to zero?

What causes the needle to assume a North and South position?

How can the turning around of the galvanometer be avoided?

What is an Astatic galvanometer?

How many needles are employed on an Astatic galvanometer?

How are they placed with reference to each other?

Does such a combination of needles point North and South? If not, give reason.

How is the coil of an Astatic galvanometer wound, and why is it so wound?

What is a compensating magnet used on galvanometers for?

What is the usual form of such a magnet, and how is it attached to the galvanometer?

Can an ordinary bar magnet be used as a compensating magnet?

What is the "constant" of a galvanometer?

Describe the Thomson galvanometer.

How is the mirror-magnet combination suspended?

What is the purpose of the mirror in the Thomson galvanometer?

What is meant by saying that the mirror, or needle, is "dead-beat"?

What are the resistances of the interchangeable coils?

Describe the features of the four-coil Thomson galvanometer.

What is the principal objection to the Thomson pattern of galvanometer?

Who was the inventor of the moving-coil galvanometer?

What is the action of a moving-coil galvanometer when current is passing through the instrument?

What is the character of the magnetic field of a moving-coil galvanometer?

A B C of the Telephone.

There are several excellent books on the telephone and its practice, but all men do not know the rudiments of the telephone. It is well, therefore, in order to gain an understanding of this instrument, as in everything else, to begin the study at the beginning. The telephone is no harder to know than any other electrical device and it becomes extremely fascinating on better acquaintance.

A B C of the Telephone is a good book for the student to start with. It explains the subject in non-technical language and the main facts connected with the telephone industry are stated in a clear and simple style. Although it is elementary in character it covers the whole subject of telephony so comprehensively and completely that after a careful study of the book the student will have a good working knowledge of the instrument and its many uses. The book is rendered particularly valuable by reason of the great many illustrations, each one of which tells a story. It has 350 pages and nearly 300 illustrations. The author of the work is Mr. James E. Homans and he is a master of the subject.

The price of this book is $1.00 per copy and copies can be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

April 1, 1912.

Delayed Newspaper Mail.

Much annoyance is caused to subscribers to this journal, as well as all other journals, living at distant points by the delay in the receipt and delivery of their copies by the post office authorities. In his zeal to put the postal service on a profitable basis Postmaster-General Hitchcock has incommoded the reading public by requiring that newspaper mail shall be forwarded to destination by fast freight. What "fast freight" means is a question. Practically, it means that our paper is delayed in its delivery in the middle western states from nine to sixteen days. All trade papers are subject to the same delay, and much dissatisfaction is expressed over the results of the postmaster-general's ruling.

The Telephone Report.

The annual report of the American Telephone & Telegraph Company, which is printed in part elsewhere in this issue, is an instructive and interesting document, and is comprehensive in scope. Apart from the facts in connection with the management and operation of the vast industry, these annual reports always contain matter of general public interest, and almost any one can read them with profit.

It is interesting to contemplate the magnitude of the operations of this corporation, and its cohesiveness is a great triumph of scientific business organization. One hundred and seventy-nine millions, five hundred thousand dollars is a sum so vast that the average mind can not grasp its material significance, and yet that is the amount the company collected from the public in return for service rendered during the past year. When one thinks of the great extent of the service and its almost universal use in this country, we begin to understand the source of this vast income. To carry on the business it required an expenditure of one hundred and twenty-eight millions, leaving fifty-one and a half millions for interest, dividends and surplus. A business of such magnitude can only be compared with that of the government itself.

The portion of the report relating to the engineering features of the industry is interesting, and shows how much the success of the business is dependent upon this department. The general public, of course, knows little or nothing about this work; all it is interested in are the results, and yet it is really the foundation of the business. Much credit is due, therefore, to the engineering skill under the initiative of progressive management, as exemplified in the present state of development in the art. The improvement of the little things is what has led to present perfection. There is no real reason why a subscriber in New York should not be able to talk with a subscriber in San Francisco; it is simply a matter of overcoming difficulties, which are constantly yielding to the power of scientific progress. Indeed, talking over such a distance is not mere fancy, it has been promised by the president of the company, and is likely to become an accomplished fact at any time.

Considerable space is given to the subject of government ownership of wire companies, which has recently been brought to public attention. The directors do not think that it is likely to become anything more than academic at least for the present, but they evidently believe that it is a future possibility, in which event, the report states, there would be no unfavorable consequences to the shareholders, other than obligatory liquidation. The directors do not believe, however, that wire communication service can be conducted as efficiently and economically by the government as by private companies.

The inter-operations of the telegraph and telephone systems are improving rapidly, the report states, and the collection and delivery of telegraph messages by telephone is becoming popular. The innovation, however, while not yet productive of economy in operation or of profit, has been of convenience and advantage to the public and there seems to be no good reason why the operating companies will not be financially benefited in time, when the facilities offered to the public for the inter-operation of the two services are utilized to a larger extent. This problem is, of course, one of public education, and both the companies concerned appear to be successful in getting the public interested in their work.

Conservation in the Telegraph Service.

The excellent articles on "Conservation in the Telephone Industry," written by Mr. P. Kerr Higgins, and now being published in these columns carry many valuable suggestions for the men engaged in the telegraph service. There are undoubtedly many small leaks in the conduct of telegraph offices which a careful analysis would disclose and for which a remedy could be devised.

Digitized by Google

Some years ago the telegraph companies left the backs of their message forms blank, and until some exponent of conservation conceived the idea of filling up this space with rules and regulations, many unscrupulous persons ordered large quantities of telegraph blanks, which were utilized for scrap paper and not for telegraphic purposes. This is one example of a large leak which was effectually stopped and there are probably many such opportunities at the present time for the application of the principles of conservation.

In the keeping track of supplies, in the supervision of office accounts and deposits, and in every department of such a large organization as the telegraph, we need the assistance of the efficiency engineer, one of whose chief fields of endeavor is the art of conservation.

Telephone Pioneers of America.

UNION N. BETHELL.

Mr. Union N. Bethell, president of the New York Telephone Company, and vice-president of the American Telephone & Telegraph Company, New York, rose from the ranks by virtue of his own energy and effort.

He entered the telephone business twenty-four years ago and worked his way rapidly and steadily to the front. For nearly eighteen years he was the operating head of the New York system, which is

U. N. BETHELL,
President New York Telephone Company and Vice-President American Telephone and Telegraph Company, New York (1888).

noted all over the world for its perfection of service. Mr. Bethell has had charge not only of the great problems of policy and finance, but also of the details of management, and to broaden his knowledge has visited Europe several times, making exhaustive studies of telephone conditions there.

Mr. Bethell was born at Newburg, Ind., about fifty years ago. He was educated at Hanover College, graduating in 1879, and later receiving the degree of A.M. from that institution. Upon leaving college he was appointed Deputy Auditor of Warrick County, Ind., and remained in that office until 1881, when he entered the government service as a clerk in Washington. There he attended the Columbia Law School, graduating in 1885. In the same year he was admitted to practice in the District of Columbia, and later in Indiana, and still later in the Supreme Court of the United States.

As a special agent of the government he spent two or three years in the West, principally Michigan, Wisconsin, Minnesota and the Dakotas.

His telephone work began in Brooklyn, N. Y., in 1888, when he entered the service of the New York & New Jersey Telephone Company. In a short time he was elected secretary and treasurer of that company, and in 1893, he was made general manager of the New York Telephone Company. His principal work was in New York, but in 1901, he was made president of the company operating in Washington, Baltimore and surrounding territory, and later of the company operating in Philadelphia and Eastern Pennsylvania. By successive steps he assumed the management of the several Bell Companies operating throughout the States of New York, New Jersey, Pennsylvania, Delaware, Maryland, and the District of Columbia, finally becoming president of the New York Telephone Company, and vice-president of the American Telephone and Telegraph Company.

For his assistance in applying the telephone to conditions in Japan, Mr. Bethell was honored in 1909 by His Imperial Majesty, the Emperor of Japan, who bestowed upon him the Order of the Rising Sun.

Electrical Instruments and Testing.

Every one connected with the telegraph and telephone service should know how to test lines and also be familiar with the instruments used in such work. It does not require much study to learn the mechanical operations of this important branch of the service, but of course a knowledge of electrical and mechanical principles involved in the design and construction of the instruments, and of the principles involved in measurements is the source of deep and never-ending pleasure to the ambitious student.

An excellent book on this subject, intended for the practical man, is "Electrical Instruments and Testing," by Norman H. Schneider, with new chapters on testing wires and cables and locating faults, written by Jesse Hargrave, division superintendent of the Postal Telegraph-Cable Company, Atlanta, Ga.

The price of this book is $1.00 and copies can be had of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York. Any other book on telegraph, telephone or general electrical subjects can be obtained at the same place.

Course of Instruction in the Elements of Technical Telegraphy—XII.

(*Copyrighted.*)

(*Continued from page 176, March 16.*)

[We began in our issue for October 16 the publication of a course of instruction in technical telegraphy. The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and is divided into chapters, following one another in logical order.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases, and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.]

Wire Resistance.

The ohm, as we have already stated, is the unit of resistance.

The resistance of a wire may vary a little with change of temperature, but it is not affected by the strength of the current flowing through it.

If a wire one mile long has a resistance of creased, his speed will be increased, but variations in his speed cannot affect the road surface, since the obstacles, or resistance, the road offers to the rider depends solely on its construction.

In a circuit, by increasing the E. M. F., the current may be increased, but the resistance of the external circuit remains the same as before; for the resistance of a wire depends solely upon its length, its thickness, and the metal of which it is made.

The resistance of a wire is proportional to its length.

If a wire one mile long has a resistance of twenty-five ohms, then two miles of the same wire will have fifty ohms resistance. It is thus a simple matter of proportion to find the resistance of any length of wire, if the resistance of a part be known.

For instance, if one foot has .002 ohm resistance, then to find the resistance of 5,280 feet, or one mile;

$$1 : 5280 : : .002 : R$$
$$R = 10.56 \text{ ohms.}$$

The resistance of a wire is also affected by its thickness.

Cut through a piece of covered copper wire and look at one of the ends. All that is visible of the conductor is a small circle of copper.

The area of this circle is the sectional area of the wire.

The area of any circle may be found by taking the square of the diameter and multiplying it by .7854.

The square of the diameter means the diameter multiplied by itself. For instance, if the diameter were three inches, the square of three would be written 3^2, and would equal $3 \times 3 = 9$.

Example. The diameter of a round copper wire is .1 in., find the sectional area.

Solution:

$.1^2 = .01$ $\quad .01 \times .7854 = .007854$ sq. in.

As the sectional area of a wire increases, the resistance decreases; or the resistance varies inversely as the sectional area.

Example. If a certain length of round wire, .1 inch in diameter, have a resistance of .5 ohm, how much will the resistance be diminished with the diameter changed to .18 inch?

Solution:

The sectional area with .1 in. diameter is

$$.1^2 \times .7854.$$

Similarly the sectional area with .18 in. diameter is

$$.18^2 \times .7854.$$

It now becomes a problem in simple proportion with the given resistance for the third term; and, as the resistance decreases with an increase of sectional area, the greater area will form the first term. We thus have the following:

$$.18^2 \times .7854 : .1^2 \times .7854 : : .5 : R$$

Cancelling the common factor .7854 and solving

$$R = 1.54 + \text{ohm.}$$

Note:

The + denotes a remainder after carrying out the division to three decimal places.

Since the common factor .7854 can always be cancelled, it may be omitted altogether, and the resistance of a round conductor is therefore inversely proportional to the square of the diameter; in other words, the resistance may be found by simple proportion if you square the diameters and remember that the larger the diameter the less the resistance.

Example. A wire .12 in. in diameter has a resistance of .6 ohm; what would be the difference in resistance with the diameter changed to .14 in.?

Solution:

Since the diameter is increased, the resistance is decreased, or

$$.14^2 : .12^2 : : .6 : R$$
$$R = .44 + \text{ohm}$$

The resistance of a piece of round copper wire .001 in. in diameter and one foot long is 10.8 ohms; find the resistance of 1,200 feet of copper wire .102 in. in diameter.

Solution:

There are two proportions here, length of wire, and thickness. Taking the length first, 1,200 feet will have more resistance than one foot, therefore the smaller length forms the first term;

$$1 : 1200 : : 10.8 : R$$

Now take the thickness.

The diameter has been increased, therefore the resistance has been decreased, or

$$.102^2 : .001^2 : : 10.8 : R$$

Combine these two into one proportion, thus,

$$1 : 1200 : : 10.8 : R$$
$$.102^2 : .001^2$$

Digitized by Google

Multiply the first terms together,

$$1 \times .102^2 = .010404$$

Multiply the second terms together,

$$1200 \times .001^2 = .01296$$

The proportion is now

$$.010404 : .01296 : : 10.8 : R$$

$$\frac{.01296 \times 10.8}{.010404} = 1{,}245 + \text{ohms.}$$

QUESTION PAPER.

(1.) A wire 10 miles long has a resistance of 275 ohms. What resistance will a foot of the same wire have?

(2.) A circuit has 500 ohms resistance, and a battery of 75 volts, what is the strength of current?

(3.) A circuit has a current strength of .02 ampere. The difference of potential developed by the battery is 50 volts, what is the circuit resistance?

(4.) (*a*) With the same external circuit if the E. M. F. be doubled will the current strength be doubled?

(*b*) Why?

(5.) A circuit has a resistance of 5,000 ohms and a battery of 100 volts. If a test relay of 150 ohms resistance be inserted at the switchboard, how much will the current be decreased?

(6.) In a circuit of 500 ohms which has a battery of 25 volts there are three 150 ohm relays. What will be the change in current strength when

(*a*) Two relays are only in circuit.

(*b*) One relay only is in circuit.

(*c*) No relays in circuit.

(7.) (*a*) Find the value of E when R = 500 ohms and I = .03 ampere.

(*b*) Find the value of R when E = 100 volts and I = .1 ampere.

(*c*) Find the value of I when E = 15 volts and R = 500 ohms.

(8.) The diameter of a round copper wire is .1 in. and the resistance of the wire .5 ohm.

If the diameter be increased to .2 in., the other conditions remaining unchanged, what will be the resistance?

(9.) What is meant by the sectional area of a round conductor?

(10.) (*a*) A battery of 25 volts generates in a circuit a current of .05 ampere. If the battery be increased to 56 volts, and the current strength consequently doubled, how will this increase affect the external resistance?

(*b*) The internal resistance?

(*c*) The circuit resistance?

(11.) The resistance of a piece of round copper wire, .001 in. in diameter and 1 foot long, is 10.8 ohms; find the resistance of one mile of similar copper wire ⅛ in. in diameter.

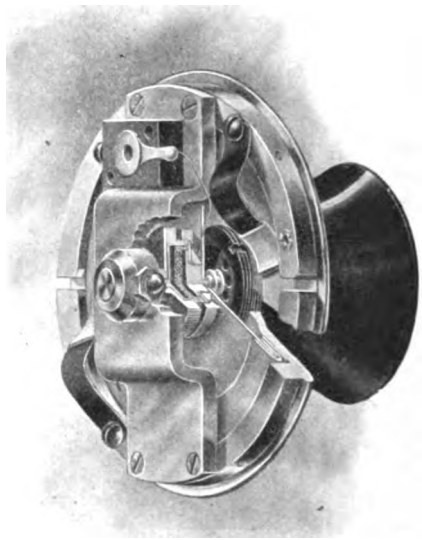
3.649 + ohms. Ans.

Alloys.—An alloy of 60 parts copper, 10 manganese, and 30 nickel has a specific resistance of 65; one of 40 copper, 40 manganese, and 20 nickel has a resistance of 150, as compared with copper = 1.

The Telephone Transmitter.

During the past decade the public has come to accept the telephone as an every day sort of thing, good for talking to some one else miles away, but owing to the familiarity which such continued speaking acquaintance has bred, has probably never given a thought to the delicate workmanship necessary to turn out a transmitter which will really talk well.

The transmitter, which is found on the great majority of telephones, is made up of fifty-nine details or parts, not including over fifty thousand granules of carbon, which are encased in a closed cup and form what might be termed the "dynamo"



THE TELEPHONE TRANSMITTER.

of the instrument. Each detail of the transmitter is made as carefully as the most delicate part of an expensive watch. The average person, rarely dealing with dimensions less than one-eighth of an inch, will scarcely realize what it means to manufacture very small parts whose dimensions must not vary more than one one-thousandth of an inch either way. The outside of the transmitter is compact appearing and strongly built.

Through the medium of these delicately manufactured Western Electric instruments, it is now possible to transmit speech from New York to Denver, Col., a distance 2,050 miles. In a short time the line will be extended to San Francisco, Cal., when, if the hopes of the telephone engineers, who are engaged in the work, are realized, the dream of trans-continental telephone communication will have come true.

The "KR" Law.

Some inquiries have been made recently as to the meaning and application of the so-called "KR" law, and as a consideration of this law is of the highest importance in the calculations of telegraph and telephone circuits we print in part an article prepared by Mr. William Finn, an electrical engineer of the Western Union Telegraph Company, New York, and published in this journal some time ago. The facts, of course, are as true now as they were when the article was first prepared, and their republication at this time will no doubt be of special interest to students of the technical course of telegraphy now running in these columns.

The distance to which it is possible to operate successfully a quadruplex circuit with a given potential is limited by the electrostatic capacity (K) and the resistance (R) of the line; the former factor tending to absorb a portion of every current wave or impulse sent into it, while the latter affects the final strength of the current flowing through it.

The number of signals that can be transmitted per second over any telegraph circuit depends upon the numerical value of its capacity in microfarads multiplied into its resistance in ohms, or upon what is known as the "KR law," which has long been understood to determine the carrying capacities of all long submarine cables, fast speed automatic circuits, etc., but the applicability of which to quadruplex working has not been so generally known or appreciated.

In telephony this particular law has played a very important part, inasmuch as it has rendered possible the calculation of the size of wire required for the successful transmission of speech. It has determined, for instance, that:

When KR = 15,000, speech becomes impossible.
When KR = 12,500, speech becomes possible.
When KR = 10,000, speech becomes good.
When KR = 7,500, speech becomes very good.
When KR = 5,000, speech becomes excellent.
When KR = 2,500, or under, speech becomes perfect, so that if a suitable value be adopted as the KR constant for any projected telephone line, it will only be necessary to select the proper kind and diameter of wire, the product of whose capacity in microfarads into its ohmic resistance will give the required standard.

Now since the KR conditions of a line have such an important bearing upon the working of telephone circuits, and, as the law pertaining thereto is equally applicable to telegraph circuits, it would seem desirable in the latter connection that, for each of the important systems in use, a KR value should also be found that would serve as a standard for determining their working capacities and the distances through which these systems could be worked direct.

In the absence of any data bearing upon the subject, the following may be interesting as affording at least an approximate idea of the efficiency limitations imposed by the KR law as applied to quadruplex working in one particular instance.

The writer was once called upon to make a test, over the Western Union lines, of a 300-pound copper wire (868 miles in length) between New York and Chicago, for the purpose of ascertaining whether, in view of its low mileage resistance, it could not be operated as a quadruplex circuit direct, that is, without the aid of a repeater in circuit.

The test was made under highly favorable conditions, the weather being fine at all points along the line, while the inductive interference from neighboring wires was comparatively slight, owing to the particular day and hour of making the experiment. The type of instrument used on the "No. 2 side" was that known as the Freir self-polarizing relay; the potentials employed being 360 volts at Chicago and 320 volts at New York. The value of Chicago's current was nineteen milli-amperes from the "short" end, and fifty-seven milli-amperes from the "long" end; the latter developing in the New York instrument an amount of magnetism considerably in excess of that ordinarily obtained in practice, inasmuch as the average full-working current on a quadruplex circuit does not exceed forty-five milli-amperes.

Despite these favorable conditions and notwithstanding the fact that the apparatus was adjusted to the highest degree of delicacy at both ends of the line, it was found impossible to secure satisfactory working signals on the No. 2 side when the distant polechanger was in operation. The effect of the "reversals" upon the second side relay cut down its working margin to an extent never before observed in the writer's experience; a result which apparently demonstrated that the advantage gained by the new wire, in respect of its low mileage resistance, was more than counterbalanced by the detrimental action arising from its increased inductive capacity.

It would appear, in fact, from the distance involved and the amount of surface exposed that the absorptive properties, or condenser-like action, of the conductor had increased in much greater ratio than the resistance of the wire had been decreased, and, as a consequence, the current waves became unduly retarded. This retardation was sufficient in amount to prevent the No. 2 relay after each "interval of no current"—from becoming energized with that rapidity and intensity necessary to counteract the tendency of its retractile spring to open the armature and thereby mutilate the signals during the aforesaid "intervals," or periods, when no magnetism is created in the receiving apparatus.

With a view to determine as closely as possible the KR conditions of the circuit, measurements were taken which showed that K = 13.4 microfarads, and R = 2,682 ohms, thus making KR = 35,938; a numerical value so much in excess of that of the regular successful quadruplex circuit as to clearly account for the difference in results obtained.

Digitized by Google

When the circuit was divided and repeatered at Pittsburgh, there was no difficulty whatever in operating all four sides of the system, although in this case the full strength of Pittsburgh's current did not amount to more than forty-one milliamperes (sixteen units less than that received from Chicago), which current, however, afforded a margin amply sufficient to allow a considerable range of adjustment on the No. 2 side without affecting the quality of the signals during the distant reversals.

The KR value of the circuit under these altered conditions was estimated at about 10,500, so that the following results may be said to have been fully established:

(1.) An excellent working quadruplex circuit when KR = 10,500.

(2.) An impracticable working quadruplex circuit when KR = 35,938, and between these two values are, of course, to be found the good, bad and indifferent grades, as well as the limiting figures representing the successful working quadruplex circuit.

According to the KR law, the speed of a current wave through wires of the same length varies inversely as the product of the inductive capacity and the resistance of their conductors. In wires similar in all respects except length, the speed of a wave in each is inversely proportional to the squares of their respective lengths, so that the carrying capacity of a wire of a given length ought to be four times as great as that of a similar wire extending through twice the distance.

As a matter of fact, the actual working capacity of a circuit divided in this way is not strictly in accordance with this rule—for reasons that need not be discussed here—but the applications of the rule nevertheless affords a clear indication of the advantage of repeatering a long telegraph circuit, the KR value of which will only be that of its longest section.

From these and other considerations the adaptability of the law to ordinary telegraphy will at once be apparent, and it may reasonably be inferred that the determination of the KR constants for aerial telegraph lines would prove as advantageous in this particular branch of electrical science as in those of telephony and cable working.

Advertising the Telegraph.

How to make the telegraph popular is a problem of prime importance in the telegraph field today, and the expedient of advertising its advantages in the newspapers is generously resorted to. The public is beginning to learn that the telegraph is so closely related to the telephone that when a person thinks of one he naturally thinks of the other also, and the two interests are now so closely related that what is beneficial to one has, generally speaking, a like effect upon the other.

With every telephone bill sent out to customers is a card to this effect: "If you want to send a telegram just take down your telephone and say 'telegram' and you will be connected with the nearest telegraph office. Then send your telegram by telephone and the cost will be charged on your telephone bill." This is an excellent way to advertise the telegraph if you have a telephone, but suppose you have no telephone how is the company going to reach you? This is the point where the press agent gets active and displays his ingenuity. The man without a telephone is not a hopeless case by any means. When he sits down to breakfast in the morning he finds his roll neatly wrapped in paper on which is printed: "If you want to send a telegram just take down your telephone receiver and say 'telegram,'" etc. As he sits in the street cars surveying the alluring advertisements of hair restorers and breakfast foods his wandering eye is likely to run up against the telegraph man beckoning to him and saying: "If you want to send a telegram just take down your receiver," etc.; and so it goes; whichever way one may turn he is likely to be informed of this easy way to send a telegram. A person with a passive disposition is sure to be profoundly impressed by these catchy suggestions, and he may even in his sleep dream of taking down his receiver and repeating the world "telegram." If he has no telephone these sugar-coated words are likely to impel him to order one put in at once so he can take down his receiver and say "telegram," and the company does the rest.

W. U. Standard Spindle File.

The engineer of equipment of the Western Union Telegraph Company, New York, has designed a standard spindle file for use on operating tables to hold messages after they have been transmitted. The spindles are ground to a chisel point, which, while allowing ready filling of the messages, offers no sharp point to injure the user.

The files are to be screwed to the tables at the left of the typewriter on a line with the back of the machine. Both ends of the spindle are alike so that if one end becomes broken or otherwise impaired it can be reversed.

United Wireless Affairs.

It is announced that the plan for reorganizing the United Wireless Telegraph Company has been agreed upon. According to Mr. A. P. West, chairman of the reorganization committee, stockholders of the United Company having more than 300,000 shares have subscribed to the reorganization plan and owners of 300,000 more shares have promised to come in on April 15, to which date the plan has been extended. There are about 1,200,000 shares in the hands of legitimate stockholders. The Chicago stockholders of the company have started a movement to organize for the purpose of protesting against the organization plan proposed, and similar movements, it is stated, have been started in other cities including Detroit, Cleveland, Buffalo and Pittsburg, where there are large holdings of this stock.

Mutilators of Telegraphy and Telephony.

BY FRANK M. EWING, ASSISTANT MANAGER TELEGRAPH DEPARTMENT, PENNSYLVANIA RAILROAD, WILLIAMSPORT, PA.

There is nothing in this world more exasperating or nerve-racking than for a train dispatcher or an operator to struggle along, quite frequently under great difficulties, trying to receive from a mutilator of the Morse telegraph code or converse with a person with indistinct articulate speech over a telephone circuit. When the quality of Morse is good it is a great pleasure to work and an experienced operator can answer questions or carry on a conversation without any discomfort, while they are receiving. If the sending is mutilated then the mechanism of the ear combines the functions of both separator and transformer, while almost every nerve is strained in order to properly translate the mutilations.

There is really no excuse for operators remaining in ignorance of their defects provided they are open to conviction. The poor senders endeavor to back up their claim of good Morse by mentioning one or two operators "who receive from them all day without breaking," not taking into consideration the fact that those patient and good-natured victims evidently familiarized themselves with their combinations and put down what they mean instead of what they send. The various characteristics of bad sending noticed are as numerous as those existing between the different styles of chirography or conversation of different people. The peculiarity of their sending lies in the lengthening of the first or last dot of a letter, running the spaced dot letters together, dropping dots off some of the letters, running some letters of words together and spacing the others, making different combinations out of them and not allowing the proper interval of time for the letter and the spaces. Thus R sounds like "Ti," C like "It," figure 3 like "V," the word coat like "Is at," them like "Thw," Emporium like "Wposium," Harrisburg like "Hasspburg," President "P R & I don't," etc., and almost every word transmitted must be deciphered by the receiving operator by making due allowance for the mutilation.

Accurate sending is more desirable than high speed. It is well to remember that operators are not judges of their own Morse, and, therefore, should not try to see how fast they can send until they have had considerable experience. Who has ever heard a mutilator admit that his sending was poor? Now and then one may concede that his speed is below standard, but as to the quality of the Morse, there can be no question, the fault is always with the receiver!

Some entertain the erroneous idea that firm transmission of the alphabet depends largely upon the pressure brought to bear on the key, and by pursuing that course do not allow the muscles of the fingers to fully relax between the formation of one dash or dot and another. The result is that a dot is lengthened into a short dash. The custom of timing for ascertaining the speed of sending should be very sparingly indulged in, for it is likely to produce careless habits.

The speed of sending should be graduated to suit the capacity of the receiver; the latter should never be crowded. Fast sending is seldom indulged in by strictly first-class operators, but fast time is made by them on account of their firm, steady, even gait.

Accept the average receiver's opinion regarding your sending before you decide for yourself that your sending is all right, for the poorest operators often think their sending is good. If the receiver tells you that you do not space properly, or calls your attention to some particular fault, do not get angry, but take the hint, and try to remedy your weak points. There should be no difficulty in correcting one's faults, as a mutilated Morse character can be detected instantly by anyone who will listen carefully to his own sending.

It was thought that the introduction of automatic transmitting machines would put a ban on the poor sender, hence his future toleration depended upon reform or a machine. Experience has shown that it simply divides mutilators into two distinct classes, those using the Morse key and those using transmitting machines. Statistics show that if a person is poor in handling one instrument, he rarely becomes an artist in handling the other. Of machine sending there is this to say: The class employing an ordinary typewriter keyboard like the Yetman transmitter, will transmit perfectly formed Morse characters provided the disks are clean and the electric contact is good, and they enable some senders who have lost their grip to do good work. The machines operated by a side motion of the Mecograph or Vibroplex type (with the exception of dot characters) require as many movements of the hand as the Morse Key.

Sending machines are trying to receivers and unsafe when not properly adjusted. They are very often so adjusted that dots are made at the rate of 80 or 100 words a minute, while the actual speed made by the operator is only 30 or 40 words a minute. Everyone, especially those at repeating stations, notices that the signals from sending machines are thin and drop out when the machines are not properly adjusted and manipulated. If a machine is properly adjusted and simply let alone it will remain so indefinitely, doing good work if proper care and judgment are exercised in handling it.

The "go as you please" sender, for whom no apology can be made, is the product of pure carelessness or indifference. He never sends two consecutive words or sentences at the same rate of speed or in the same style, and is never sure of a word until he hears the last letter completed and is then so surprised at his execution that he usually stumbles all over the word that follows.

Telegraph repeaters can be adjusted for both light and heavy senders, but not for an uneven sender. A telegraph repeater adjusted for either a light or a heavy sender might be out of adjust-

Digitized by Google

ment for a perfect sender. In sending, the motion of the key should be directly up and down, avoiding all side pressure. Never of course, allow the fingers or thumb to leave the key; that is, do not tap, pound, or strike the key with the fingers, or allow the elbow to leave the table.

Since the typewriter has come into general use, there is no danger of worrying an experienced operator by sending too fast. A good typewriter operator can write from sixty to seventy words a minute and more, but an expert telegraph operator cannot send steadily over forty-five or fifty words a minute; consequently a receiver has plenty of time, in addition to writing the message, to insert the "time received," the operator's personal sign, etc., even when receiving at the fast rate mentioned. Every young operator should learn to operate the typewriter rapidly and accurately.

Mutilations and misunderstandings occur in telephony as well as telegraphy.

The letters T, V, B, P, and the words Weaver, Stever, Lever, confined, consigned, are difficult to distinguish over a telephone on account of the similarity in the pronunciation. I know of a message boy in receiving a message over a telephone about a car of brick that was consigned from Newberry to Harrisburg, Pa., received the message that the care of brick was "confined" to Harrisburg. The sound of the letter "S" in the word consigned was lost in transmission. On some railroads with two towers "P" and "B" misunderstandings have occurred over the telephone in getting the two towers mixed due to the similarity in the pronunciation of the letters "P" and "B." Quite frequently a doctor is called by telephone to see a patient and calls at the wrong house going many blocks out of his way on account of indistinct articulation or similarity of the pronunciation of names. Persons with an impediment in their speech who are not a success in speaking over a telephone circuit, make good telegraph operators and transmit good Morse. When the telephone receivers are off the hook any noise in the vicinity of the telephone passes through the transmitter making it difficult to receive conversation. When telegraph keys are open no noises pass out over the circuit.

Variable Condenser for Wireless.

A very serviceable variable condenser can be made, says Mr. John M. Blake in the *Electrical World*, by combining a number of fixed condensers which are graded in an ascending geometric series. It is essential that each step in the series should add the steps that have gone before; otherwise, the condenser would have much too sudden changes of capacity.

This form of condenser gives us a command in tuning which the rotary form of condenser does not fully meet, for the reason that after a satisfactory beginning has been made in adding capacity in the first part of the rotation the rest of the motion up to a half circle adds very little to the increase. The last quarter of a turn only doubles the capacity. With this system of fixed condensers the ratio of increase is constant, and each step is equally effective. Besides this, the capacity can be made quite large with very little weight as compared with the ordinary rotary plate form. The trial condenser actually made had a ratio of three to four increase, or thirty-three per cent.

The members were built up of measured areas of thin metal and foil, separated by freshly dipped sheets of paraffine paper. They would necessarily vary from the standard on account of accidental variation in distance of separation. Besides this, a serious error was made by not noting that a rolled condenser acts on both sides, while a folded or convoluted one has much less of the surface active. Notwithstanding these drawbacks, the result was very satisfactory, and the general working was excellent. The changes of capacity were not sufficiently sudden to be much noticed.

The series started with an active area of 0.6 sq. in. and increased about 300 times in twenty-one steps. An extra step was reserved for a short-circuit. The first member was a strip of brass 0.3 in. wide and 1 in. long. This was made active on both sides. This first member represents the sum of the series of smaller areas which, let it be imagined, have gone before, but which have not been developed. The next member, which gave an increase of one-third by its addition to the first, was 0.1 in. wide and 1 in. in length. Several of these small members, properly insulated, were placed between a folded brass sheet. This made them more compact and manageable. The remaining condensers were built up singly of tinfoil.

The series following deviates a little from the standard in order to make it more simple and to avoid fractions; 0.3; 0.1; 0.1; 0.2; 0.2; 0.3; 0.4; 0.6; 0.8; 1; 1; 2; 2; 3; 4; 6; 8; 10; 10; 20; 20. While this series will give practical results for a home-made condenser, it is probable that something more perfect would be expected from an instrument maker. It would seem that an ideal construction could be had by using a twenty-five per cent. increase series, with each member approximately adjusted for capacity. This should secure an even flow. This series would have the advantage that ten steps would represent ten times increase, the tenth root of ten being very nearly five-fourths.

The commutator used consisted of a row of springs or pins arranged in a little less than a half circle of 1-in. radius. These pins rubbed on a half-circular brass plate mounted on a short cylinder of wood. A pointer on top of the box rotated this cylinder upon a central peg. The details of connecting and arranging the condensers about the commutator and of packing all in the containing box need not be gone into. It is important to add a short-circuit step at the top of the scale. Puncture by atmospheric discharges would probably be in the main prevented by bridging with a short spark-gap. The pressure of the springs in the switch can be so adjusted that the movement of the pointer at 3-in. leverage is smooth and easy. This feature, together with the sustained rapid change of capacity, will be found to invite a free use of this variable condenser while tuning.

The Dot-and-Dash Alphabet.

In an interesting article in the *Century Magazine* for March, Mr. Edward L. Morse, of Stockbridge, Mass., son of professor S. F. B. Morse, inventor of the telegraph, presents newly discovered documentary evidence that the dot-and-dash telegraph alphabet was invented by his father.

Mr. Morse takes as the basis of his article the claims made by the late F. L. Pope, that many of the essential elements of the telegraph were the invention of Alfred Vail, including the dot-and-dash alphabet.

In 1895, Mr. E. L. Morse published a series of articles in the *Electrical World*, in which he says, "I was able to bring forward enough documentary evidence to prove to all but the most biased partisans, that Morse, and not Vail, was the inventor of the dot-and-dash alphabet." Since that time, Mr. Morse states, he has from time to time, and even quite recently, discovered further corroborative testimony, so that the matter can now be settled for all time.

"I must also disclaim any intention of casting discredit on the character of Alfred Vail," says Mr. Morse. "It is not with what he has claimed for himself, but with what is claimed for him, that I take issue.

"The first idea of his great invention," Mr. Morse continues, "was conceived by Morse while he was returning from Europe in 1832, on the packet-ship *Sully*, and he jotted down in his sketch-book, a certified copy of which is now in the National Museum in Washington, his first ideas, which are the basic principle of the telegraph of today.

"Among other things, the dots and dashes appear, but only to represent numerals, not letters. The alphabet does not come on the scene until some years later, but there can be no disputing the point that the dot and dash of the 1832 sketch-book were the embryo from which the alphabet was afterward developed.

"It was on Saturday, September 2, 1837, that Alfred Vail of Morristown, N. J., first saw the crude instrument which Morse, through lack of means, had been compelled to construct (most ingeniously, by the way) from an old canvas-stretcher and a wooden clock.

"Vail was impressed with the possibilities of the invention, and from this time, or, rather from September 23, 1837, was associated with Morse in the perfection of the mechanical parts of the invention, the latter paying him in the only way possible at that time, by making him a partner in the enterprise.

"Morse's first idea for the sending and recording of intelligence, as we shall see, was to use only numerals, corresponding with words in a specially prepared dictionary, and it was not until after his association with Vail that this plan was abandoned and the alphabet appeared, *although conceived and written before he met Vail.* It is from this circumstance that the confusion has arisen."

Mr. Morse then states first all the evidence that the advocates of Vail have been able to bring forward, and then the evidence on the Morse side, and then goes on:

"I have here given everything that I have been able to find bearing directly on the claim of Vail's advocates that he was the inventor of the code. Nowhere, to my knowledge, in any of Vail's letters or diaries, and these were voluminous, does there appear a written claim, or even a hint, on his part, that he had anything to do with the code. On the other hand, he vigorously claims the invention of the dry-point to emboss the characters, an ingenious, but now discarded, part of the instrument. In letters to Morse, moreover, he many times speaks of 'your system of marking, lines and dots.'

"Now let us see what we can find among the papers and letters and published writings of Morse to substantiate his claim. I say his claim, for he never refers to it except as (my conventional alphabet), and to those who knew Morse's scrupulous regard for the truth, this would be enough; but I have found among his papers many scraps of evidence to prove conclusively that he was claiming only what was his just due, and I shall here give some of the most important.

"The following is written in pencil on a scrap of paper, a method often employed by Morse in making the first rough draft of letters or articles:

" 'It is quite common to misapprehend the nature and extent of an improvement without a thorough knowledge of an original invention. A casual observer is apt to confound the new and the old, and, in noting a new arrangement, is often led to consider the whole as new. It is therefore necessary to exercise a proper discrimination lest injustice be done to the various laborers in the same field of invention.

" 'I trust it will not be deemed egotistical on my part if, while conscious of the unfeigned desire to concede to all who are attempting improvements in the art of telegraphy that which belongs to them, I should now and then recognize the familiar features of my own offspring and claim their paternity.'

"While this has no date, and evidently refers to some later attempts at improvement, I have introduced it as showing Morse's desire to do justice, and also as a very plausible explanation of Baxter's mistake in looking upon Vail's mechanical improvements as new inventions.

"The next note is also in pencil, with a few words added or interlined in ink, but all in Morse's handwriting:

" 'Mr. Vail in his work on the Telegraph at p. 32 intimates that the saw teeth type for letters as he has described them in the diagram (9) were devised by me as early as the year 1832. Two of the elements of these letters, indeed, were then devised, the dot and space, and used in constructing the type for numerals, but so far as my recollection now serves me it was not until I had experimented with the first instrument in 1835, that I added the — dash, which supplied me with the three elements for combination for letters. It was on noticing the fact that when the circuit was closed a longer time

Digitized by Google

than was necessary to make a dot, there was produced a line or dash that, if I rightly remember, the broken parts of a continuous line as the means of imprinting at a distance, were suggested to me; since the inequalities of long and short lines, separated by long and short spaces gave me all the variations or combinations of long and short lines necessary to form the alphabet. The date of the code complete must therefore be put at 1835, and not 1832, although at the date of 1832, the principle of the code was *evolved.*'

"Here we have a definite claim in writing by Morse that his alphabet was devised in its first form two years before Vail came on the scene, and the opinion that Vail knew this, but had placed its invention at an earlier date than was historically correct, a proof of Morse's earnest desire to claim only what was his.

"Another pencil memorandum is even more illuminating:

"'It was believed for some time (even after the telegraphic alphabet had been composed and practically tested), that reducing the despatch to numbers (the numbers being those of the words in a specially prepared dictionary), would be found most convenient in practice; this numerical mode being in point of rapidity of transmission far beyond any previous mode of communicating intelligence at a distance. But it was soon perceived to be indispensable that alphabetic characters and not numbers, especially for proper names, should be adopted, and experience has proved the superiority of the alphabetic code for all purposes of communication. Consequently when experience had demonstrated the eligibility in practice of the alphabetic mode, the Morse code was ready and completely prepared for use in anticipation, it required no modification but the 4 or 5 combinations of the dot and dash which have been substituted for the "*spacc letters*" and the addition of new and special combinations for the additional letters in other languages than the English (the German and Russian for example).'

"This is certainly very clear and conclusive," says Mr. Morse, "but lest some skeptic may urge that this note, without date, but evidently written some time after the alphabet had come into general use, was a disingenuous attempt on the part of Morse to claim more than was his due, let us see if we cannot find evidence of a much earlier date."

Mr. Morse then introduces a letter from a certain Mr. Tracy, and other correspondence bearing on the subject, and says, in conclusion:

"To sum up in a few words the evidence on both sides: Vail has nowhere left a written claim, or even a hint, that he had anything to do with devising or modifying this telegraphic code, whereas he did leave a written claim to the invention of the dry-point for embossing the characters on the tape, and in his book on the telegraph he makes several claims. In view of these claims on Vail's part, the contention of his advocates that he remained silent with regard to the alphabet because of his contract with Morse falls to the ground.

"Morse, on the other hand, as we have seen, has specifically claimed in writing that he devised the code in its first form two years before Vail had heard of the telegraph, and Mr. Tracy's letter is corroborative evidence. He has left written proof of having occupied himself with the simplification of the code, and he never fails to refer to it as 'my conventional alphabet,' while Vail, in the letter of April 20, 1848, and in other letters, refers to it as 'your system of marking.'"

The article contains several illustrations, including facsimile reproductions of the most important documents referred to.

New Book.

TELEPHONY. By Samuel G. McMeen and Kempster B. Miller. 948 pages, 671 illustrations. Chicago: American School of Correspondence. Price $4.00.

This latest addition to the literature on the telephone has a decided advantage in being the product of two men whose knowledge of and experience and reputation in telephony are unquestioned. They are both among the most active and leading telephone men of the time, and what they say regarding the art may be accepted as authoritative and up to date.

The book is designed with the care that comes from knowledge and experience, and is a complete exposition of the art of telephony, both in theory and practice. Every drawing used was especially prepared for this work, and each one has the valuable merit of being clear and distinct.

The work has fifty-three chapters, Chapter forty being devoted to telephone train dispatching. A partial list of other subjects treated of in the various chapters includes: History and development, acoustics, lines, transmitters, receivers, primary cells, electromagnets and inductive coils, condensers, selective and non-selective party-line systems, protective means, switchboards, private branch exchanges, intercommunicating systems, traffic; phantom, simplex and composite circuits, lines, cables, poles, etc., underground construction, wiring, testing, etc. From this list an idea may be gained of the scope of the work, and railroad men will be especially interested in the book by reason of the special chapter on telephone train dispatching, which describes in a general way the various systems in use.

Copies can be procured of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York, on receipt of price.

Grievances of English Telegraphers.—At a recent meeting of the London branch of the Postal Telegraph Clerk's Associtaion, a resolution was unanimously adopted protesting against the great increase in the late duties at the Central Telegraph Office, and the alleged disregard of the operators' comfort and convenience by the controlling officers.

Mr. J. C. Duane, district plant superintendent, Western Union Telegraph Company, Jacksonville, Fla., writes: "I could not get along without TELEGRAPH AND TELEPHONE AGE. It is very instructive and contains lots of interesting news to me."

CONSERVATION TALKS NO. 3.

BY P. KERR HIGGINS, OKLAHOMA CITY, OKLA.

Development.

The lack of development work by managers is wasted time. Few, if any, managers there are who have not some "dead time" on their hands and do not know what to do with it. The trouble is that only about 30%, if that much, of the managers of telephone plants have the commercial instinct. They dislike collecting, and canvassing, and either leave this important duty alone or delegate it to others.

Telephone economic efficiency consists of (1), maintaining the plant, (2), giving the service, (3), getting the money, (4), developing new business and holding the present patrons.

In developing new business, good judgment must be exercised to get only paying business, *i. e.*, development work should not be done when new investment would be necessary without proper authority.

In development work, the manager should strive to have the co-operation and help of every employe of the company and frequent meetings of employes should be held with the co-operative end in view. When business is secured it should be cared for promptly. To hold old business and get new business the following basic principles should be borne in mind: (1), efficiency, (2), economy, (3), dispatch and (4), honesty in management.

Such will result in (1), the best service possible at fair rates, (2), adjustment of differences promptly and fairly. Reasonableness on the part of the company results in reasonableness on the part of others, whether regular or transient patrons. The personal appearance of employes and of companies' offices are also great factors in development. Develop neatness and avoid "frills."

Managers should keep posted on up-to-date methods, and the company should assist and encourage them along these lines by frequent booster bulletins and tables comparing his exchange with others of a similar class and character.

The manager should have data showing the commercial details of his plant. This should be in the form of maps, records, etc., showing work done, present and prospective patrons. He should be a member and regular attendant at and worker in the commercial club and active in assisting in every proper manner the development of the town or city.

It is also well for him to be an active member and worker in one or more of the best fraternal societies, church work, etc., using discretion to get into the channels that will make him a better man and a more valuable employe. The people who patronize the telephone, as a rule, are not frequenters of pool rooms and like resorts.

He should be a "telephone man" who knows his business thoroughly. He should cultivate an even temper and a smiling face regardless of the abuse which must be heaped upon him by those not familiar with conditions and often unreasonable in their demands because of this.

The company, on the other hand, should encourage the manager; there will be plenty of others to slap him in the face and discourage him.

The work of development should be thoroughly systemized so that no time is lost in beginning a new day's development work.

Be courteous, it costs effort, but pays big dividends. Satisfy your patrons if possible and practicable to do so.

If advertising is authorized see that it is truthful, consistent and proper. If you do not get up your own copy and do not like it, say so.

Be above criticism and strive to make and keep the public and the company proud of you.

Progress.

BY JOHN F. SKIRROW, ASSOCIATE ELECTRICAL ENGINEER, POSTAL TELEGRAPH-CABLE COMPANY, NEW YORK.

How often we hear the complaint "Oh, if I only had—almost anything you could name—how much better off I'd be," and then there is a sigh, and not infrequently a comparison with the lot of someone whom the complainer considers more fortunate.

Quite often the question is asked, "why don't you take — something the complainer already owns—and fix that over, or improve it, for the purpose in mind?" The answer comes, "That old thing; why I'd be ashamed of it. I wouldn't waste my time on it. If I can't have the very newest and latest I don't want any."

Far be it from the intention of the writer to deprecate the abandonment of the outworn or antiquated, for of all men the engineer perhaps best knows the value of a judicious use of the scrap pile in the furtherance of both present economy and future progress. The thought, however, that obtains in so many minds that everything old and dingy or not of the latest type is not worth house room is a poverty-breeding germ.

"Take what you have and make it better" is a good slogan for both business and home affairs, and if you use your powers of observation you will notice that those who follow this precept make continual progress, and hold the ground they gain. It is also noticeable that these same people are often eventually in a position to invest in "worth while" new things that the "all-new or nothing-for-me" folks seldom attain.

Try the application of this precept to your office and home affairs, and you will soon find waste eliminated and secure an attitude of mind that will make for real progress. Fix up what you have—clean it up—improve it—the difference between new and old is often merely a matter of paint or elbow grease. Don't talk or think about displacing what you have until both the need for the new and its worth have been demonstrated beyond question.

Mr. Alfred Williams of Wichita, Kan., in renewing his subscription, writes: "I find TELEGRAPH AND TELEPHONE AGE most interesting and instructive. Kindly continue sending me the paper."

Reinforced Cement Poles.

Among the troubles met with in the manufacture of reinforced cement poles, is holding the reinforcement in place, and its tendency to separate from the concrete when the pole is subjected to uneven strain. These, and other difficulties, are claimed to be overcome, in the Rubello-Santi system of pole construction.

In this construction the reinforcement is held rigidly in position as though it were one piece, and the concrete may be applied with the reinforcement in an upright position for large poles or in a horizontal position for smaller sizes, with no danger of displacing the reinforcement.

The spacing or reinforcing rings or squares hold the entire reinforcement at predetermined distance from the walls of the mold, producing a uniformity in the concrete surrounding the reinforcement, and a corresponding uniformity in resistance against strain in any direction. The rings have a powerful binding effect, which prevents the concrete from crushing or shelling off.

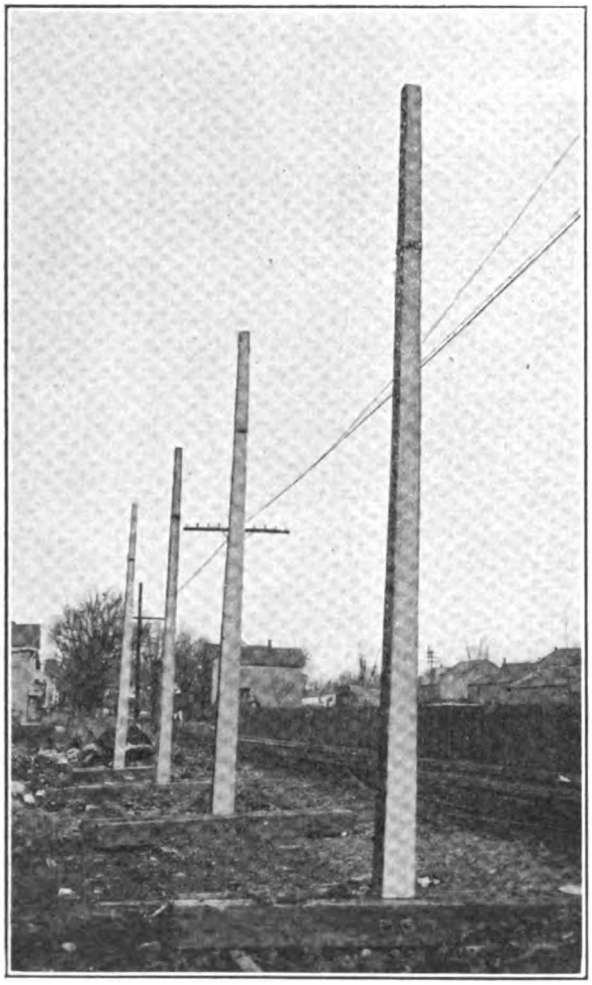

FIG. 1.—ROW OF THIRTY-FOOT POLES ERECTED IN BOGGY GROUND.

Fig. 1 shows a line of concrete poles erected in boggy ground and Fig. 2 shows the method of reinforcement with steel rods held in place by spacing rings. This method of reinforcement is adaptable to either solid or hollow poles, and the patents thereon are owned and controlled by the Standard Cement Pole Company of America, 25 Broad Street, New York.

Pole License Sustained.—The Illinois supreme court has sustained the decision of the appellate court in the case of the city of Springfield vs. the Postal Telegraph-Cable Company. The decision holds that the imposition by a city of a charge against telephone and telegraph poles is not a tax, but is a license properly imposed by the city in the exercise of its police powers.

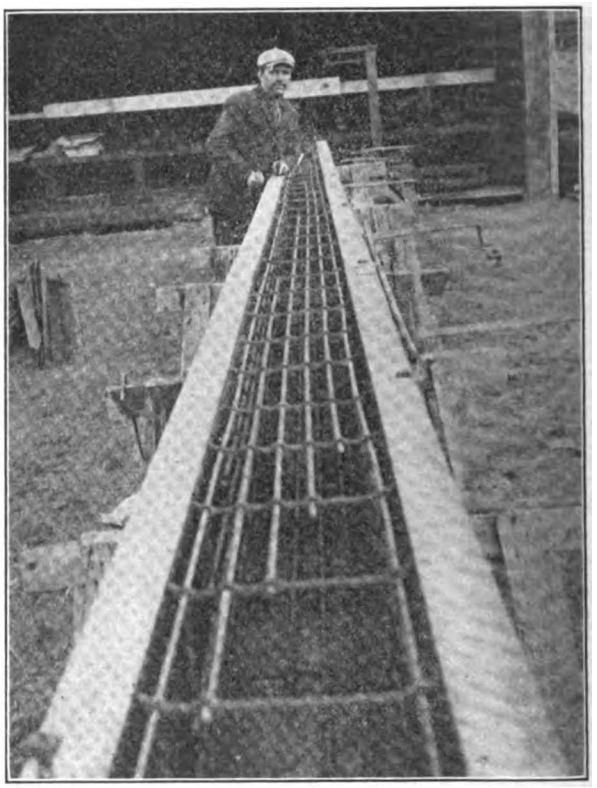

FIG. 2.—MOULD SHOWING DISTRIBUTION AND METHOD OF REINFORCEMENT WITH STEEL RODS HELD IN PLACE BY SPACING RINGS.

Helps for the Business Man.—There are to-day many business men who unfortunately for themselves are doing without many things which would enable them to work in greater comfort and, in general, conduct their business with increased efficiency. That such a state of affairs exists is not the fault of the business men, but rather due to the fact that they have not been told in the right way. Realizing this, the Western Electric Company has recently published an attractive little book aptly named "The Silent Partners—A True Story." The book is written in an easy, colloquial style, and the advantages of Western Electric inter-phones as time and step savers; of desk, bracket, ceiling and counter fans as creators of coolness; of ventilating or exhaust fans as fresh air producers and of large and small motors for shop and factory use, are cleverly set forth.

The Transmitter Battery

IN the early days of the telephone, considerable difficulty was experienced in devising a transmitter which would regulate the current in the transmitter circuit, in unison with the sound waves until Edison, in 1877, invented the carbon transmitter.

This invention was a long step forward in the perfection of the telephone, and the improvement in transmission was marked. If you are using a type of Primary Battery that supplies a fluctuating current, you can effect an improvement in transmission approximating that brought about by the invention of the carbon transmitter, by using EDISON-BSCO Primary Cells for talking circuits.

EDISON-BSCO Cells are eminently suited for this service, because they do not polarize and are of extremely low internal resistance; therefore, they give perfectly uniform voltage throughout their entire life on transmitter work, whereas, dry cells quickly polarize, even at low discharge rates, resulting in fluctuation in the potential and reduction of the intensity of the magnetic field.

EDISON-BSCO Cells are now made in various styles, ranging in capacity from 200 to 400 ampere hours, or sufficient to give continuous service on way station 'phones, for instance, of from two to five years or more under average conditions of service on one charge, without renewal or other attention.

The strongest argument favoring the use of these cells is the improvement effected in the service, for the reasons explained above, but aside from this, the question of economy deserves consideration. The cost of active material consumed by EDISON-BSCO cells represents only about one-third the cost of dry cells, on similar circuits, and the long life of the Edison cell reduces the expense for labor to the minimum.

The Railroad.

Mr. L. S. Wells, superintendent of telegraph of the Long Island Railroad, New York, has resumed duty after an absence of several weeks on account of illness. He is now fully recovered.

Convention of Railway Signal Association.—The Railway Signal Association held its Spring meeting in Chicago on March 18. The next convention of the association will be held in New York some time in June. C. C. Rosenberg, of Bethlehem, Pa., is the secretary.

New Copper Telephone Circuit on Lackawanna.—The Lackawanna Railroad recently put in operation a second commercial telephone circuit, between its general office in New York and Scranton, Pa., using 350-pound copper wire. This circuit will be extended to Buffalo in the near future.

Bronze Tablet in Memory of Mr. Harriman.—A large bronze memorial tablet is to be placed by the directors of the Erie Railroad Company, in the station at Harriman, N. Y., in memory of the late E. H. Harriman, the well-known railroad manager. It is at the Harriman station where the so-called Turner Monument is to be erected on May 2 to commemorate the sending of the first train order by telegraph.

The Turner Monument Fund.

The bronze tablet of the Turner monument is now on exhibition at the office of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York, and all interested are cordially invited to call and examine this excellent bronze product of the sculptor's art.

Thursday, May 2, has been selected as the day for the dedicatory ceremonies.

The monument fund now stands as follows:

Previously acknowledged, $2,325.09; James Kent, manager Canadian Pacific Railway Companies' Telegraph, Montreal, Que., $5.00. Total, $2,330.09.

Train Dispatching by Telephone in the South.

During the past few months a number of Southern railroad systems have decided to adopt the telephone for dispatching their trains and to discard the telegraph. There are eighteen Southern railroads using the telephone at present, with about 7,800 miles of line so equipped, and a total of fifty-six circuits, equipped with a little over 1,500 selector way stations. The new roads to join the ranks of the telephone users are the Central of Georgia, which is equipping a 160-mile stretch, with thirty-one stations, the Florida East Coast, which has just about completed the installation of 478 miles of line, covering four circuits and forty-six stations, the Atlanta & West Point, which is about to equip 225 miles of line with thirty-one stations, the Piedmont Traction Company, which is equipping twenty-four miles of line with both selector and selectively operated semaphore equipment, the Gulf, Florida & Alabama, where 100 miles of line with twenty stations is to be installed, and the Greenville, Spartanburg & Anderson Railway, which has ordered selector and selectively operated semaphore equipment for fifty-eight miles of line and nineteen stations. All of these roads use the Western Electric Company's apparatus.

Meeting of Railway Telegraph Superintendents in Chicago.

A joint meeting of the Eastern and Western Divisions of the Association of Railway Telegraph Superintendents was held in the assembly room of the Chicago & Northwestern Railway, Chicago, on March 20.

A meeting of the Committee on Wire Crossings was held in the office of general superintendent of Telegraph, W. W. Ryder, of the New York Central Lines, on March 19, and discussed fully the question of proposed agreements.

At 2:00 p. m., March 19, the Executive Committee held a meeting at the Pennsylvania Railroad Company's office, at which it was decided to change the date of the next annual meeting, which is to be held in New York, June 4, on account of the former date being so near the National Republican and Democratic conventions. It was also decided to make the Waldorf-Astoria the headquarters, but the meetings will be held in some building other than the hotel. The change in date of the annual meeting was announced by president G. A. Cellar at the divisional meeting.

The association has received an invitation to visit the Edison plant at West Orange, N. J., and it has also been decided to hold a banquet at the Waldorf during the convention, or a shore dinner at the Country Club, on Travers Island, New York.

At the divisional meeting there was a general discussion in reference to the telephone, and the chairman of the topics committee made an urgent appeal to the members for papers to be read at the convention. Mr. W. W. Ryder is to furnish a paper on the operation of the telephone and Mr. L. B. Foley on the economies of the telephone on the Delaware, Lackawanna & Western road.

A number of the members visited the Manufacturers' Exhibition which was being held at the Coliseum.

Mr. W. J. Camp, assistant manager of telegraphs, Canadian-Pacific Railway, Montreal, Que., denied emphatically the newspaper statement that the Canadian-Pacific had abandoned the use of the telephone for train dispatching, etc., and stated that they were moving the dispatcher's headquarters from one point to another, which necessitated changing the resistances at the different offices, and, therefore, the offices were temporarily out of service.

Among the superintendents present were E. A. Chenery, Missouri Pacific Railway, St. Louis, Mo., who presided; W. W. Ashald, Grand Trunk, Montreal, Que.; Wm. Bennett, Chicago and Northwestern, Chicago, Ill.; F. E. Bentley, Terminal Railroad Association, St. Louis, Mo.; C. W. Bradley, Chesapeake & Ohio, Richmond, Va.; W. J. Camp, assistant manager of telegraphs, Canadian Pacific, Montreal, Que.; G. A. Cellar, Pennsylvania Lines West of Pittsburgh, Pittsburgh, Pa.; M. H. Clapp, Northern Pacific, St.

Walker, Denver & Rio Grande, Denver, Col., and W. C. Walstrum, Norfolk & Western, Roanoke, Va.; and the following associate members, W. L. Cook, Chicago; A. P. Eckert, New York; A. G. Francis, Chicago; W. E. Harkness, New York; E. E. Hudson, Orange, N. J.; B. A. Kaiser, New York; M. E. Launbranch, Chicago; H. E. Merrell, New York, and A. D. Smith, Montreal, Que.

Mr. P. W. Drew, superintendent of telegraph, Minneapolis, St. Paul & Sault Ste. Marie Railway, Chicago, Ill., is secretary of the association.

Testing on Railroad Telephone Circuits.

BY K. W. ENDRES, NEW YORK.

GENERAL.

An essential part of every wire circuit transmitting electricity is a means of locating trouble on this circuit with some degree of accuracy This holds true whether the line in question be carrying heavy currents for power purposes or the almost infinitesimal currents used in transmitting speech. Tests are a necessity in both cases. They are more necessary in the case of telephone circuits than with power circuits, because the former are of a small size of wire with correspondingly lower tensile strength and are, therefore, more liable to breakage.

In a modern telephone office the testing facilities form a very important portion of the equipment. Arrangements are made so that all opens, crosses, leaks, grounds, and in fact every possible kind of trouble can be accurately and quickly located. With the multiplicity of lines entering a telephone exchange this is important and the methods used are rather elaborate. With railroad circuits the need for such tests is just as important, but owing to the smaller number of circuits, much simpler apparatus can be employed.

CLASSES OF RAILROAD TELEPHONE CIRCUITS.

In dealing with railroad telephone circuits they may be divided into two general classes. The first of these covers the telephone train dispatching circuits and others of the same type; for instance, message circuits which also employ the selective signaling system. The second class are the railroads' ordinary private lines which may be in the nature of long distance circuits or may consist merely of short lines extending from the different private branch exchanges owned by the company. Under these two headings the matter of testing will be treated in these papers.

TRAIN DISPATCHING LINES.

The telephone circuit as applied to train dispatching is somewhat of the nature of a long distance circuit. It has, however, very important differences from the ordinary commercial telephone circuit which, as we all know, is merely a pair of copper wires with a telephone set at either end. The train dispatching circuit consists, likewise, of a pair of copper wires extending in length from 30 to 400 miles or more, but having bridged across it at frequent intervals, telephone and selector equipment placed at the different way-stations along the railroad's right-of-way.

Each one of these stations is called selectively, and it is possible with the circuit arrangement employed for any number of telephone sets to be connected across the circuit at any one time. As a matter of fact, probably there are never more than from six to ten operators listening on the line at once.

In this railroad work on train dispatching circuits the object of prime importance is to keep at least one through circuit in operation—no matter what happens to the others. The shorter, less important lines are sacrificed in times of emergency for the benefit of the one circuit that counts. This, needless to say, is the train dispatching wire. A railroad is in business to keep its trains moving, and, as long as this can be done, all the other circuits can be neglected for the time being.

(To be continued.)

Western Electric's Business.—Goods billed by the Western Electric Company during February totaled about 2 per cent. less than for February, 1911. The first two months of the current year indicate a total business for 1912 of approximately $67,000,000. Sales for 1911 totaled $66,300,000. In several lines, notably in sales to companies outside of the Bell interests, business last month was the best for any one month in the company's history. Bell estimates of telephone construction requirements during 1912 call for a total of slightly over $55,000,000 of new work.

UNITED TELEPHONE COMPANY

OUR HIGH POWER TRAIN DESPATCHING SETS

Having the operative parts supported upon an adjustable arm, replace the unsatisfactory and dangerous "Head Receivers" and eliminate induction noises and dangers of lightning discharge.

Provided with a non-metallic megaphone, the volume of tone is greatly increased, distinct enunciation secured, and the effort of constant listening released.

Controlling the main line and local circuits by a semi-automatic switch, operated by the foot, the operator's hands are free for other work and battery waste is prevented.

This apparatus is provided with a transmitter of the power required for the service.

For Prices and Further Information Address Board of Trade Building, Boston, Mass.

Obituary.

J. C. Dye, a lineman for the Postal Telegraph-Cable Company at Cumberland, Md., died March 19.

Robert C. Daw, aged 30 years an operator for the Western Union at Denver, Col., died in that city March 6.

D. C. Thompson, aged 47 years, cashier of the Western Union Telegraph Company at St. Joseph, Mo., died at that place on March 12.

Frank Benton, a blind telegrapher, died at York, Pa., March 16. Messages to be transmitted were read to him, and in receiving he copied on the typewriter.

Charles H. Currier, aged 76 years, for many years manager of the Western Union Telegraph office at Fort Wayne, Ind., died in that city March 10. He retired from the telegraph service ten years ago.

Isabel Bamford, wife of Richard L. Bamford, superintendent of telegraph of the New York Stock Exchange, died in New York on March 24. The funeral services and interment were held at Valcartier, Quebec, Canada, her former home.

Charles W. Henderson, aged 68 years, a well-known telegrapher in New England, died in Dorchester, Mass., on March 20. He was for twenty years manager of the Western Union office in Boston. Ten years ago he was appointed solicitor and claim adjuster, and last summer was retired on a pension.

W. C. J. Edwards, aged 49 years, until recently with the Commercial Cable Company at Boston and Rockport, Mass., died in Boston, on March 12. He was a native of England. The funeral services, which took place on March 14, were attended by superintendent F. H. Putt and Mr. Frank Wilson, formerly superintendent of the Commercial Cable Company, Boston.

F. J. Krumling, manager of the Western Union Telegraph office at Toledo, Ohio, fell dead at his desk on March 7. Mr. Krumling was born in Toledo, February 21, 1859, and lived there the greater part of his life. He was operator for the Associated Press in St. Louis, Mo., between 1883 and 1888, when he returned to Toledo. In 1903 he was appointed chief operator and in 1908 manager of the office.

The Late H. H. Matlock.

H. H. Matlock, whose death at Springfield, Ill., on March 6, was announced in our issue for March 16, is the twelfth member of the Society of the United States Military Telegraph Corps to pass away since the Atlantic City reunion last September. He was employed in the war department at Washington with Col. A. B. Chandler, Chas. A. Tinker and David Homer Bates, and was highly esteemed by these gentlemen.

Mr. Matlock was on the private telegraph staff of Secretary of War Stanton and while occupying this position he became acquainted with President Lincoln through a message which Mr. Lincoln sent to Col. Haupt, at Alexandria, Va., on August 30, 1862. On receiving the reply to the message, which was of a quieting nature, Mr. Lincoln laid his hand on Mr. Matlock's shoulder and remarked: "This takes a great load from my mind." Mr. Matlock asked permission to keep the original message, to which Mr. Lincoln agreed, after endorsing it.

Telegraphers' Aid Society.

The New York Telegraphers' Aid Society's financial statement for the year ended March 6, is as follows:

Balance on hand March 6, 1911	$25,077.16
Receipts	6,838.60
Total	$31,915.76

DISBURSEMENTS.

Sick Benefits	$4,183.76	
Death Benefits	1,300.00	
Expenses	771.88	6,255.64
Balance on hand March 6, 1912		25,660.12
Total		$31,915.76

RELIEF FUND.

Balance on hand March 6, 1911	$ 5,404.64
Receipts	1,034.94
Total	$ 6,439.58
Disbursements	511.15
Balance on hand March 6, 1912	5,928.43
Total	$ 6,439.58

"Bugs" and Bug Hunters.

The average operator is constantly confronted with the possibility of a physical breakdown resulting from the continuous strain upon his mental and nervous energy, and when that condition is reached his days of usefulness are over. The wise operator of today appreciates this fact and does not wait for his arm to give out before getting a sending machine, commonly known as a "bug." Many of the best positions in the telegraph service today are held by operators, the majority of whom are using a standard, up-to-date sending machine.

It is true that many operators, so broken down that they cannot send on a Morse key, are now sending rapidly and with ease on a transmitting machine. The standardized transmitter of this type is unquestionably the best investment an operator can make. It means insurance to his arm, on which his livelihood depends. It gives him greater efficiency and puts him in line for promotion, and last, but not least, it saves him sixty per cent in labor compared with hand sending.

The selection of a reliable sending machine is not a difficult matter. At the present time the Mecograph Company, Cleveland, Ohio, has on the market a machine called the "Mecograph Premier," which is a practical instrument, of excellent workmanship and is simple and scientific in design. This machine overcomes all the

Digitized by Google

objections to sending machines. There is no chance for split dots. The adjustments are extremely simple and can be made instantly for long or short distances on multiplexed wires.

D. Van Nostrand Company, the well-known scientific book publishing house, has moved from 23 Murray and 27 Warren streets, to larger and better quarters at 25 Park Place, New York.

T. M. B. A. Assessment.—Assessment No. 536 has been levied by the Telegraphers' Mutual Benefit Association to meet the claims arising from the deaths of E. N. Cobb at Houston, Tex., E. N. Dennis and W. L. Allen at Richmond, Va., and E. L. Graul at Philadelphia, Pa.

LETTERS FROM OUR AGENTS.

NEW YORK WESTERN UNION.

"Senator" Wm. L. Ives having fully recovered from his recent illness has resumed duty and is once more in full control of his circuit, 151 East, which he has handled continuously for the last twenty-five years.

The annual election of the New York Telegrapher's Aid Society was held on March 26 and the following officers were elected: President, A. M. Lewis; vice-president, J. F. Zeiss; treasurer, T. M. Brennan; financial secretary, C. A. Kilfoyle; recording secretary, Mary E. Saunders. Executive Committee: J. F. King, J. J. Keefe, D. H. DeBaum, A. J. Gilman. Auditors: F. J. Nurnberg, J. F. E. Hopkins and H. M. Heffner. The annual meeting of the society was held March 27.

Mr. T. M. Ragen, assistant Southern traffic chief, has resigned and has left New York to settle on the Pacific Coast.

Mr. N. B. Maresca has been appointed manager of the 426 Columbus Avenue office, vice W. A. Sanford, resigned. Mr. E. S. Lonergan has been appointed manager at 70 Eighth Avenue, vice R. Brown who has been transferred to the managership at Fourteenth Street and Third Avenue, in place of Mr. M. W. Russnow, resigned.

Mr. W. E. Heady, of the general operating department, has recently been transferred to the executive offices of the company as stenographer.

The Morse Dramatic Club, a recently organized society, consisting chiefly of members of the telegraph fraternity in New York, will play "The Professor's Secret," a four-act comedy, by Robert M. Baker, Friday evening, April 12, at Murray Hill Lyceum, 34th Street and Third Avenue, New York. Dancing will follow the performance. There will also be several other interesting features, and, judging from the interest taken, the event promises to be a success. The following operators will take parts in the play: W. J. Keegan, W. F. Packard, Stanley Gross, Joe McGivern, Alphonse Hirsch, Nonita Dooley, Helen Mahoney, Florence Webber, and Margaret Curran. All are employed at 195 Broadway, except Mr. Hirsch who is now engaged in other business.

NEW YORK POSTAL.

Mr. T. V. Rhates, formerly of the Pennsylvania Railroad, New York, has been appointed manager of the 696 Columbus Avenue office vice A. Butscher who has been transferred to the 944 Broadway office.

PHILADELPHIA POSTAL.

The sympathy of the entire office is extended to repeater chief Chas. S. Almes upon the sudden death of his mother.

HOUSTON, TEX., WESTERN UNION.

J. A. McNabb, traffic chief, has resigned to assume a position at the key. He has been with the company at this point nearly thirty-five years and has made an enviable record. He served as wire chief for over fifteen years. He was presented with a gold handled umbrella by his associates upon his retirement from the floor as a token of appreciation of his gentlemanly and courteous treatment.

It is a valuable privilege to be eligible for membership in a sound and reliable life insurance association which cannot afterwards cancel or alter the terms of the certificate issued. The payment of the sum called for in a benefit certificate blesses alike the recipient and the provider. The Telegraphers' Mutual Benefit Association, 195 Broadway, New York, now the oldest co-operative life insurance association, having been in successful operation for the past 43 years, offers this privilege to all eligible employes of telegraph and telephone service. Write at once for application form and full particulars.

FOR SALE.—Yetman Transmitter without typewriter attachment. Perfectly new. The best transmitting device on the market. Address, Yetman, care of TELEGRAPH AND TELEPHONE AGE, New York.

Wanted—Second hand Hudson word register and an old style Vibroplex. J. S., 3521 Florida Ave., Evanston, Cincinnati, Ohio.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

The Milliammeter in Connection with Multiplex Operation.

The milliammeter is an instrument used for measuring current in a circuit and it will also indicate its polarity. Owing to its extreme sensitiveness to minute fluctuations in the current, and to the reliance which may be placed upon the accuracy of the readings as indicated by the needle's deflection, its use in connection with the handling of bridge duplexes and quadruplexes, where it is permanently connected in the bridge in series with the polar relay, is now considered almost indispensable. Not that it takes any part in the actual operation of the apparatus, but as a guide which enables the attendant to balance the apparatus and otherwise work in a more intelligent and confident manner. Without the aid of a milliammeter the attendant is compelled to do more or less guesswork in some situations, and at best, is not sure of the degree of success he has attained, with no other guide than that of "sound" or "feel," to direct him, as is always the case, when balancing without it.

To prove this statement let us take for an illustration the operation of obtaining a "static" balance. Assume that an ammeter is connected in the circuit as usual, but that the attendant disregards it temporarily and endeavors to eliminate the effect of the line discharge by the sense of sound, or "feel" alone. If he is not an expert, or particularly well informed, he may conclude that he has eliminated the disturbance entirely the moment the "kick" disappears, whereas he may possibly have only weakened its power in so slight a degree that interference is merely smothered to a point just below the danger mark, and he is none the wiser. If he had been guided by the needle of a milliammeter he would have noticed that although the sounder failed to respond, the needle would still have continued to be affected, thus indicating that the compensation was not complete. He would, therefore, have continued his readjustments until the deflections ceased and would have thus created a wider margin between interfering and non-interfering conditions. Of course an expert, by the sense of touch, might have reduced the strength of the remnant discharge a little more, but he could not by that means judge to what degree.

The deflections of the needle enable one to work more intelligently, as previously stated, for the reason that the direction of its swing indicates the direction in which the attendant should work. For example, when he closes his key to produce a static "kick," he knows, or should know, if he has read the instruction papers furnished him, that in the standard arrangement of negative polarity for the "marking" current, if the needle is jerked upward, or in a spacing direction, it indicates that more capacity must be added to the condenser, and *vice versa*, diminished if it swings in the opposite direction. Hence he proceeds to insert or remove the condenser plugs as is required without having to resort to the old method of trial balancing in order to ascertain his bearing.

The milliammeter will also indicate which side of a repeater station a long two-section circuit has "failed," when an interruption occurs, by indicating normal deflections of the needle when the trouble is beyond, and abnormal deflections when the trouble is on this side of the repeater. Without a meter the location of the fault is more or less a matter of guesswork until the repeater attendant reports, as the situation must otherwise be judged by the character of the signals made on the relay by operating the home key, and as these vary in accordance with the nature of the trouble they are often misleading.

In conclusion it may be stated that so much reliance is now placed on the accuracy of the readings and actions of the needle in every situation met with in connection with bridge duplex and quadruplex operation, that its adaptation has possibly led to the adoption of the present standard method of balancing directly to the distant

Digitized by Google

battery instead of to a "ground" as the old method required; thus eliminating the time previously lost waiting for the repeater attendant to come in and turn the switch.

Personal.

Mr. C. C. Marsh, general manager of the Mecograph Company, Cleveland, Ohio, was a recent business visitor in New York.

Dr. L. M. Rheem, the well-known, old-time telegrapher of Minneapolis, Minn., formerly, and for many years a prominent citizen of Omaha, Neb., has been elected manager and secretary of the Helena, Mont., Commercial Club.

Mr. A. B. Banker, an old-time New York telegrapher but for the past fifteen years identified with the Paul Smith Hotel property at Paul Smith's, N. Y., was a recent New York visitor and made his visit the occasion to call on many of his old time friends.

Mr. David Homer Bates will deliver a lecture on "Lincoln in the Telegraph Office," at Wadleigh High School, One Hundred and Fifteenth St. between Seventh and Eighth Aves., New York, April 16, at 8 p. m. Members of the telegraph and telephone professions and their friends are cordially invited to attend. Admission free.

Mr. A. S. Duncan and Mr. A. Podmore, members of the National Telephone Company's engineering staff, who were transferred to the English Post Office, have been appointed assistant electrician and assistant engineer respectively to the Constantinople Telephone Company, and will shortly proceed to Constantinople to take up their duties.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. Jesse Hargrave, division superintendent of the Southern Division of this company, with headquarters at Atlanta, Ga., was in Buffalo, N. Y., on March 30 where he examined the new and up-to-date equipment of that office. He was accompanied by Mr. J. P. O'Donohue, division electrical engineer, New York.

Mr. F. W. Conger, division superintendent of the Mackay Telegraph-Cable Company, with headquarters at Dallas, Tex., who has been in New York for the past two weeks on business connected with the service, returned to Dallas, April 5.

Postal Charges Against Telephone Companies.

The New York Telephone Company has investigated the charges made by the Postal Telegraph-Cable Company that the Bell Companies in various parts of the United States are diverting the business intended for the Postal Company to Western Union offices. The Postal Company charges that when its patrons call upon the telephone and ask for the Postal Company for the purpose of telephoning telegrams they are often connected with Western Union offices instead, and many instances are cited as proof that the practice is general.

The New York Telephone Company states that it has instructions posted in its Cortlandt Street Exchange regarding this matter. When the call is merely the one word "Telegram," the order is to give the call to the Western Union. But if a call comes in "Telegram, Postal," then the connection is made with the Postal line.

If in any case it is not done, the company asserts, it is an operating error which may be the fault of the user of the telephone, who might say "Telegram" in a clear voice and "Postal" in an indistinct voice. But where the request is for the Postal, it is stated, the connection always will be made.

Mr. E. J. Nally, vice-president and general manager of the Postal Telegraph-Cable Company, New York, issued a statement in which he says:

"The telephone company says the reason why the Postal's business has been diverted to the Western Union is because the telephone operator made a mistake. I should like to ask how does it happen that the same mistake is being made all over the United States of late? Telegrams have been handled by telephone all these years and the Postal Company has impartially received its share until very recently; all of which bears evidence of an intent and not a mistake. Is it reasonable to suppose that the telephone girls would divert our business in such country-wide fashion unless they had been encouraged to do so? The trouble is with the new policy of the telephone company and not with the telephone girls.

"Then the telephone company says that the Western Union has advertised that its messages will be received by telephone. So has our com-

Digitized by Google

pany advertised, but the people who read our advertisements and who attempt to send messages by the Postal lines are given the Western Union office instead of the Postal office.

"The whole argument of the telephone company in its answer is too flimsy to convince any one.

"I have issued instructions to our thirty-six superintendents throughout the United States," Mr. Nally said, in conclusion, "to make complaint to the Public Service Commissions in their respective states where these things continue to occur, and we shall see whether this discrimination can be carried on indefinitely."

Magnetic Club Spring Dinner.—Arrangements have been completed for the spring dinner of the Magnetic Club, which will be held at Mouquin's, on Fulton Street, New York, on April 24. The guest of honor will be Hon. William A. Prendergast, Comptroller of the City of New York, who will address the Club. The location of the meeting place is central and a large attendance is expected. Mr. W. B. Dunn, 253 Broadway, New York, is the secretary of the Club.

W. S. Hallett, Superintendent of Supplies, Postal Telegraph-Cable Company, New York.

Mr. W. S. Hallett, acting superintendent of supplies of the Postal Telegraph-Cable Company, New York, was recently appointed superintendent of supplies for the same company. For several years he was connected with a firm of provision brokers, and, after the firm wound up its affairs,

W. S. HALLETT,
Superintendent Supplies Postal Telegraph-Cable Co., New York.

he entered the employ of the Postal Company, in October, 1895, in the supply department where he has since continuously remained. He has filled the positions of clerk, storekeeper and chief clerk, and was appointed acting superintendent of supplies on the death of W. D. Francis in August, 1911.

Mr. Hallett was born in Provincetown, Mass., December 20, 1868. His long and varied experience in the supply department of the Postal Company eminently fits him to assume the added responsibilities placed upon him.

Miss Nally Sponsor for the "Jouett."—Miss Marylee Nally, daughter of Mr. E. J. Nally, vice-president and general manager of the Postal Telegraph-Cable Company, New York, has been selected by the Navy Department to act as sponsor for the U. S. S. *Jouett*, at Bath, Me., on April 15. Mr. Nally, together with his entire family, was present at the launching. Miss Marylee was the favorite of the late Admiral and is related to him, her grandfather and Admiral Jouett being sisters' children.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr G. M. Yorke, engineer of this company, New York, was in Detroit recently on business connected with the service.

Mr. W. N. Fashbaugh, traffic engineer, together with Mr. S. B. Haig, general supervisor of traffic, New York, have returned from Denver, Col., where they took part in the general conference of western officials of the company.

Mr. H. C. Worthen, general superintendent, Atlanta, Ga., announces that the position of division commercial superintendent of the Southern Division has been discontinued. Mr. J. M. Stephens, who formerly filled that position, has been appointed assistant general superintendent of the Southern Division with headquarters at Atlanta.

A conference of district commercial superintendents was held in New York, April 6. Among those present were C. F. Ames, Boston, Mass.; A. C. Terry, Pittsburgh, Pa.; J. W. Reid, Philadelphia, Pa.; J. F. Nathan, and W. A. Sawyer, New York.

Mr. Shirley M. English, president and general manager of the Postal Telegraph-Cable Company of Texas, Dallas, Tex., was a recent New York business visitor.

Mr. H. W. Drake of the office of the engineer of equipment, New York, is in Chicago on company business.

L. J. Maxwell, district superintendent, Jacksonville, Fla., has been appointed a member of the executive committee by President W. S. Jordan, of the Old Time Telegraphers' and Historical Association.

Mr. W. F. Orr, district commercial manager for western Massachusetts and Vermont, Boston, Mass., has been appointed acting manager of the Boston office, vice O. A. Conner, resigned.

Mr. J. E. Rowe, chief operator of the Nashville, Tenn., office, has been promoted to a position in the general traffic department of the company, with headquarters at Atlanta, Ga. Mr. T. B. Adams has been appointed to succeed him as chief operator at Nashville. Mr. Adams has been identified with the Nashville office for over twenty years beginning his telegraph career as a messenger.

Digitized by Google

Mr. F. R. Veale, chief operator at Richmond, Va., was a recent executive office visitor in connection with the cable service.

A three days' conference of traffic representatives was held at the Albany Hotel, Denver, Col., beginning March 20. The meeting was presided over by Mr. W. N. Fashbaugh, traffic engineer, assisted by Mr. S. B. Haig, assistant traffic engineer, New York, Mr. J. C. Nelson, general superintendent, and Mr. B. L. Brooks, division traffic superintendents, Denver, Col. The following were in attendance: Messrs. W. J. Lloyd, division traffic superintendent, J. J. Welch, district traffic superintendent, M. J. Duggan, overland division chief, and C. H. Finley, chief operator, Chicago; R. W. Kean, district traffic superintendent, Minneapolis, Minn.; W. H. Strong, chief operator, St. Paul, Minn.; W. J. Armstrong, district traffic superintendent, St. Louis, Mo.; H. C. Chace, division traffic superintendent, H. J. Jeffs, district traffic superintendent, and H. S. Converse, chief operator, San Francisco, Cal.; G. D. Hood, district traffic superintendent, Seattle, Wash.; R. H. Miller, district traffic superintendent, Los Angeles, Cal.; J. C. Smith, division Commercial and traffic superintendent, W. P. Davis, district commercial superintendent, and W. S. Strawbridge, chief operator, Dallas, Tex.; H. Vandevender, district commercial superintendent, New Orleans, La.; J. W. Brooks, district commercial superintendent, Oklahoma City, Okla.; E. C. Labadie, district traffic superintendent, and L. P. Grover, chief operator, Salt Lake City, Utah; E. S. Peterson, chief operator, Helena, Mont.; J. P. Barnhart, district traffic superintendent, C. B. Horton, district commercial superintendent, and J. W. Dudley, chief operator, Omaha, Neb., and W. G. Bennett, chief operator, Wichita, Kan.

Mr. C. F. Ames, district commercial superintendent of the Western Union Telegraph Company, Boston, Mass., made an address March 22 before the Bangor Chamber of Commerce, Bangor, Me., on the evolution of the telegraph. Mr. Ames' address was historical in character, and touched upon the methods employed by man, to signal between distant points, from the earliest times to the present. Modern telegraph methods were fully described and the lecture made a deep impression upon the audience. It was effectively illustrated by lantern slides. Mr. Ames addressed the Lewiston, Me., Board of Trade on the same subject on March 28.

Cities Have Right to Regulate Stringing of Wires.—In the action brought by the Western Union Telegraph Company against the city of Richmond, Va., a decision was handed down by the Supreme Court of the United States upholding the right of cities to regulate the stringing of telegraph wires.

Subscribe for TELEGRAPH AND TELEPHONE AGE. It is the leading paper of its class in America.

Importance of Engineering Societies.

Mr. W. E. Athearn, engineer of equipment, Western Union Telegraph Company, New York, on March 28 delivered an address before the New England Telephone and Telegraph Society, Boston, on the utility and importance to employes of engineering societies, and their relations to the present and future needs of handling business. He encouraged all those present to make suggestions to their superior officials in matters where they thought the service could be improved; the companies, he said, want suggestions.

There was a large and attentive audience and a full discussion followed Mr. Athearn's address.

The Cable.

Dinner to Mr. Sherry.—On March 30 the New York staff of the French Cable Company gave a dinner to Mr. Frank J. Sherry, auditor, to celebrate the twenty-fifth anniversary of his service with the company.

Report of Central and South American Telegraph Company.—The report of the Central and South American Telegraph Company for the year ending December 31, 1911, shows that the gross business was $1,646,931, as compared with $1,755,166 during the year 1910. Expenses amounted to $698,226, compared with $700,224 in 1910, leaving a net amount of $948,705. Out of this, dividends of $574,260 were paid which left $374,445 surplus, as against $480,682 for 1910. The total surplus of the company at present on hand is $2,607,919.

The Mexican Telegraph Company reports for the year ending December 31, 1911, gross earnings of $946,907, as compared with $939,109 for 1910. Expenses, taxes, repairs, etc., were $192,207, and $45,500 were paid to the Mexican government. After deducting dividends of $358,940 there is a net surplus of $350,259, which, as against $361,941 for 1910, combined with the surplus of preceding years, gives a total of $2,935,376.

Proposed Rehearing of Dick Patent Case.—Attorney-General Wickersham has made application to the Supreme Court on the part of the United States government for leave to intervene and for a rehearing of the Dick patent case, which recently was the subject of a decision by that court of far-reaching effect on inventors and manufacturers in general. In support of its application, the government states that the Dick case is not limited in its significance and consequences to the parties of record, but is of the gravest import to the people of the United States and concerns the government in a number of cases, civil and criminal, now pending, for the enforcement of the anti-trust laws.

Many subscribers find some one special article in TELEGRAPH AND TELEPHONE AGE alone worth more to them than the subscription price of the paper which is $2 per year.

The Telephone.

Mr. Union N. Bethell, president of the New York Telephone Company and vice-president of the American Telephone & Telegraph Company has been elected a director of the Western Electric Company to succeed Mr. F. R. Wells.

Mr. Bancroft Gherardi, engineer of plant, American Telephone & Telegraph Company, New York, on March 19 addressed the Telephone Society of New York on the subject of "Telephone Transmission."

Mr. Charles F. Mason, formerly of the Postal Telegraph-Cable Company, New York, has been appointed division commercial superintendent of the Pacific Telephone & Telegraph Company with headquarters at Los Angeles, Cal.

Mr. Charles Kinyon, repeater operator of the American Telephone & Telegraph Company, at Oklahoma City, Okla., has been advanced to the position of test board man at Joplin, Mo.

Mr. J. W. Wilson, district general commercial superintendent of the Pioneer Telephone & Telegraph Company at Arkansas City, Kan., died on March 30. Mr. Wilson entered the service in 1885 and through his knowledge of the requirements of the business obtained by diligent study he occupied at various times many of the most important positions in the service of the company. He was a member of the Telephone Pioneers of America.

New Telephone Exchanges in London.—Three new telephone exchanges are in course of construction in London for the relief of exchanges which are heavily loaded.

Independent Telephone Company's Interest Default.—The Interstate Independent Telephone & Telegraph Company, of Chicago, has defaulted on the semi-annual interest due on its $2,200,000 first mortgage 5-per-cent. bonds.

New York to Dallas by Telephone. — Telephone conversation was held recently between New York and Dallas, Tex. The test was made over two routes, one circuit going by the way of Chicago and the other via Philadelphia and St. Louis. The Chicago circuit was 2,500 miles long, but gave better results than that over the St. Louis route, which measured 2,000 miles.

Chinese Telephone Operators.—The San Francisco Chinese telephone office has, at present, 1,284 subscribers. The young ladies who operate the switchboard are Chinese, but speak English fluently, as on calls outside of the Chinese exchange they are required to pass the number in English.

Emergency Telephone List.—The Cumberland Telephone & Telegraph Company, New Orleans, La., uses the first inside page of its directory for an emergency list, containing the telephone numbers of hospitals, the various police precincts and police and fire headquarters.

Dr. A. G. Bell an Editor.—Dr. Alexander Graham Bell has assumed the editorship of the *Volta Review* at Washington, D. C. This paper has been published for thirteen years by the American Association to Promote the Teaching of Speech to the Deaf, an organization founded by Dr. Bell. A new department dealing with scientific problems will be a feature of the paper under Dr. Bell's direction.

Government Telephony in Japan.—Government ownership of telephones in Japan cannot be cited as an instance of efficient and speedy service. The average lapse of time between the signing of the contract for service and the actual installation of the instrument is, it is stated, about three years. This situation has created a new profession, that of the telephone broker, who purchases the prior right of installation from one person and sells it to another who is in more urgent need of the service.

Switchboard for Deaf Mutes.—A telephone for the deaf and dumb was recently exhibited by William E. Shaw, of Lynn, Mass. It comprises an electrical keyboard, differing slightly in appearance from that used on a standard typewriter. This is connected with a signal board on which are thirty-six incandescent lamps, the bulb end of each of twenty-four globes bearing a letter of the alphabet, while twelve of the bulbs bear the numerals. With two or more outfits in place and connected together, should one mute wish to call up another he presses a key, which lights a lamp on the signal board. Upon receiving a return signal, he begins to talk by pressing the various levers on his keyboard. The instrument was invented by Mr. Shaw and his wife, both of whom are deaf mutes.

The Telephone the Cause of High Cost of Living. — The high cost of living and the causes thereof form subjects for endless speculation, and the causes assigned are as numerous as are individual ideas on the subject. A dealer in dairy products recently testified before the Food Investigating Committee in New York, that the telephone was to blame for the high prices of foodstuffs. He said that the department store custom of educating customers not to carry their purchases home and to a great extent to have their orders transmitted by telephone has become so general that consumers have extended this method of shopping to include marketing. So many small orders are received by telephone, he said, that the cost of delivering them exceeds the profit of their sale. As a consequence prices go up. Other retail dealers accused the telephone also, and said that a customer finds use of the telephone so convenient that it is seldom a full order is contained in one message. This means it was said, that two and more deliveries to the same houses, instead of one, must be made.

Telephone Pioneers of America.

Mr. Theo. N. Vail, president of the Telephone Pioneers of America, New York, was, on March 26, presented with a handsomely framed group-portrait of the Telephone Pioneers taken on the occasion of the organization meeting in Boston, November 3, 1911. On the frame is a silver plate suitably inscribed. The souvenir was presented by Secretary Henry W. Pope, on behalf of the executive committee and in acknowledging its receipt President Vail thanked the committee for it and stated that he would treasure it very much.

The Transmission of News.

In an address before a recent meeting of the New York Telephone Society, Mr. S. M. Williams, manager of press service, Western Union Telegraph Company, New York, gave some interesting facts regarding the early and modern methods of transmitting news. The first recorded transmission of news, he said was in 1084 B. C., about 3,000 years ago.

Coming down to the time of the invention of the telegraph by Prof. Morse, Mr. Williams pointed out how quickly the telegraph was availed of for the transmission of important news, after the first line was opened to the public.

"Every school history," he said, "tells about the first dispatch transmitted over the Morse electric telegraph—that on May 27, 1844. There was sent over the line between Washington and Baltimore these words: 'What hath God wrought?' But the first news dispatch is less well known.

"Morse, with the aid of a $30,000 appropriation by Congress, had built a telegraph line between those two cities. Just as the work was completed, the Democratic National Convention met in Baltimore. On May 29, 1844, two days after the What-hath-God-wrought message, the convention on the eighth ballot nominated James K. Polk for president. Alfred Vail had made all arrangements for a spectacular demonstration in connection with the convention. Nowadays the newspapers would class it as a press agent stunt.

"There were no wires run into the convention hall, but a hustling messenger plan was fixed up, so that the moment it was apparent that Polk had the necessary votes, a message was telegraphed to Washington, where the wire terminated in the capitol and the news was announced on the floor of Congress. Then there went back over the wire this message:

"'The Democratic members of Congress to their Democratic brethren in convention assembled send greetings. Three cheers for James K. Polk.'

"This was read out in the convention before the cheering for the winner had died down or the announcement of the result officially made by the presiding officer."

Referring to the National Convention to be held in Baltimore in June, he said:

"The wire traffic loads from Baltimore during this convention will be particularly heavy, because of the proximity of a number of the largest cities of the country. Newspapers in New York, Philadelphia and Washington will treat it almost as a local event and, if the proceedings are at all interesting, will give more columns of space to it than to conventions at more distant points. The very low toll rates, both for telegraph and telephone, from Baltimore to these three cities will induce a liberal use of the wires for dispatches and conversation. In this service the new underground cable from New York to Washington, now just completed, will play an important part."

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. The review of Maver and Davis' book. "The Quadruplex," was completed in our issue for February 16, and the next book to be taken up and treated in like manner is "Electrical Instruments and Testing," by Norman H. Schneider, with chapters on testing wires and cables and locating faults, by Jesse Hargrave, a well-known and capable electrical engineer. These subjects will no doubt prove of great interest to students, as they are timely and important, and each student should have a copy of the book at hand in order to follow intelligently the study of the subjects under consideration.]

GALVANOMETERS (Continued)

What type of galvanometer is the D'Arsonval instrument?

How are the coil and mirror of the D'Arsonval galvanometer suspended?

What is the advantage of this particular form of construction?

What is the relation of the deflections to the current?

What is the character of the moving system of this galvanometer?

What is the ballistic type of galvanometer adapted for?

State the difference between a dead beat and a ballistic galvanometer.

What are the principal features of the wall galvanometer?

What is the sensibility of the wall instrument shown in Fig. 12?

Are the D'Arsonval galvanometers affected by external magnetic fields?

State the reasons why.

How are the oscillations of a galvanometer mirror read?

RHEOSTATS.

What is a rheostat?

What special properties are requisite in the wire used in rheostats?

How are the rheostat coils wound, and why are they so wound?

How does the current flow around rheostat coils?

Why should the binding posts of rheostats be made large?

What means are employed to vary the resistances of rheostats?

What is the principal disadvantage of the plug switch?

In selecting metals for resistance wires what properties should they possess.

In the manufacture of high resistance wires is any standard alloy preferred?

Name some of the resistance wires in common use.

What alloys seem to be generally preferred by instrument makers?

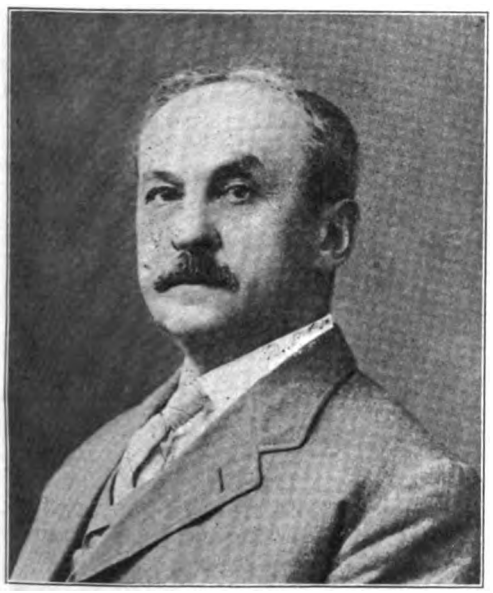
Telephone Pioneers of America.

J. N. KELLER

Mr. Jasper Newton Keller, president of the New England Telephone & Telegraph Company, Boston, Mass., is one of the best known of the Telephone Pioneers, and has achieved a wide reputation as an able and progressive executive officer in the telephone field. The New England company under Mr. Keller's administration has been highly successful and serves a large and important area of the country in the most approved manner.

Like many other successful telephone managers, Mr. Keller was graduated from the telegraph ranks, where are found those essential elements that combine to make the successful business man. Mr. Keller is a native of Iowa, being born in Burlington on January 22, 1846. His first experience in telegraphy was in Mansfield, Ohio, entering the service about the year 1862. After varied experiences in the west he became general agent of the Union Pacific Railroad at Ogden, Utah, where he was one of the founders of the Ogden Telephone Company. He next went to Texas and Arkansas where he filled the positions of general superintendent, general manager and vice-president of the Southwestern Telegraph & Telephone Company, which he built. About 1884 he moved to New England where he now occupies the position of president of the

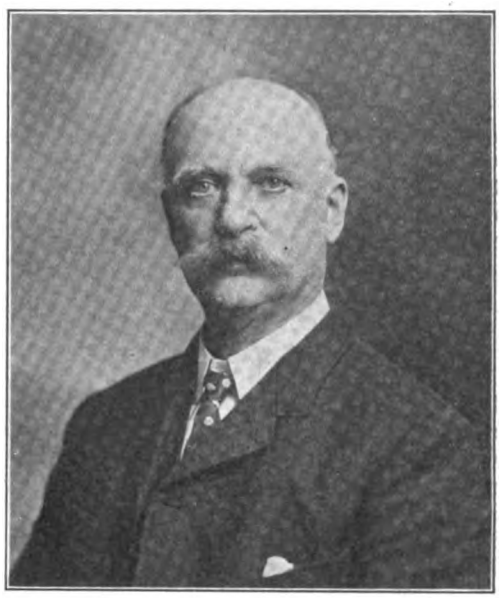


JASPER N. KELLER,
President New England Telephone and Telegraph Company, Boston, Mass. (1879).

New England Telephone & Telegraph Company, with headquarters at Boston. It is of interest to note that Mr. Keller has a son who is also a Telephone Pioneer—Mr. C. T. Keller, general commercial superintendent of the New England Company, Boston.

C. R. TRUEX.

Mr. Charles R. Truex, special agent of the commercial department of the American Telephone and Telegraph Company, New York, is well-known to telephone men, both pioneers and



CHARLES R. TRUEX,
Special Agent, American Telephone and Telegraph Company, New York (1879).

moderns, through his long association with the telephone service, and especially through his activities in connection with the organization of the Telephone Pioneers of America. He, with Mr. Henry W. Pope, secretary of the Association, and Mr. Thomas B. Doolittle, conceived and carried out the idea of organizing an association of telephone pioneers, and the fruition of their thought and labors was realized on November 2, 1911, when the organization of the Telephone Pioneers of America was effected in Boston.

Mr. Truex was born in New York City, September 3, 1845. On October 1, 1879, agreeable to an arrangement with Mr. Theo. N. Vail, general manager of the National Bell Telephone Company, Mr. Truex engaged with that company to exploit and establish the telephone exchange business in different sections of the country, and as a special agent of the National Bell Telephone Company started the telephone exchange business at various places in Connecticut, Pennsylvania and the west and reorganized and stimulated many others.

Following the consolidation of exchanges which were merged into companies operating large territories he represented the American Bell Telephone Company on the executive committee and board of directors of the Philadelphia Bell Telephone Company, the Central District and Printing Telegraph Company, the Pennsylvania Telephone Company, the Central Pennsylvania and Supply Company, the New York and Pennsylvania Telephone Company, and others.

Digitized by Google

January 1, 1893, he was appointed general contract agent of the American Telephone and Telegraph Company and remained in charge of that department until 1908 when the department was abolished, after which he became attached as a special agent of the commercial department, New York, of which Mr. Henry Stanford Brooks is the commercial superintendent.

The Turner Monument Dedication.

The monument now being erected at Harriman, formerly Turner, N. Y., to commemorate the sending of the first train order by telegraph, will be dedicated on May 2, under the direction of the chairman of the committee, Mr. E. P. Griffith. Following is the order of exercises: Opening prayer by the Rev. J. Holmes McGuinness, rector of the Episcopal Church at Arden, N. Y.; singing of "America"; address by Mr. H. D. Estabrook. Mr. David Homer Bates will present the monument to the Erie Railroad Company, and then the monument will be unveiled by Miss Gertrude M. Griffith, daughter of Mr. E. P. Griffith. President F. D. Underwood, of the Erie Railroad, or his representative, will accept the monument for the railroad company, after which the Ode to Morse, by Mr. Marion H. Kerner, of New York, will be sung. The exercises will then be closed by the Rev. J. Holmes McGuinness.

Mr. Andrew Carnegie has been invited to be present at the unveiling, and if it is possible for him to attend he will do so. His private secretary, Mr. Jas. Bertram, says, in a letter to Mr. David Homer Bates: "Mr. Carnegie's movements are so uncertain he cannot positively accept, but he is anxious to be present and will attend if practicable."

Mrs. E. H. Harriman, of Arden, N. Y., in a letter to Mr. E. P. Griffith, accepts for herself and family the invitation to be present at the dedication.

The bronze tablet for the monument which was on exhibition in the office of TELEGRAPH AND TELEPHONE AGE was viewed by several hundred persons and much admired. It has been shipped to Harriman and has been affixed to the monument.

All railroad, telegraph or telephone employes and dependent members of their families entitled to transportation, can obtain the same over the Erie Railroad to attend the dedication ceremonies by making application in the usual way.

Messrs. E. P. Griffith, D. H. Bates, Chas. Keck, and J. B. Taltavall, visited Harriman, April 10, and witnessed the attachment of the bronze tablet to the granite monument. The monument is now ready for the dedication ceremonies. It occupies a commanding position near the station and will attract the attention of passengers on passing trains. A more satisfactory site could not have been found, and the committee is highly pleased with the selection.

The Reid Memorial.

The James D. Reid Memorial Committee, New York, has prepared a pamphlet for general distribution giving brief accounts of Mr. Reid's relations to the telegraph, a sketch of his life and a history of the movement to erect a suitable memorial to commemorate his life and telegraph work. The frontispiece consists of an excellent autographed portrait of Mr. Reid. Subscriptions toward the memorial fund are solicited.

The officers of the Memorial are: Charles P. Bruch, president; Col. A. B. Chandler, treasurer, and W. B. Dunn, secretary.

The executive committee consists of David Homer Bates, William J. Dealy, James R. Beard, Lewis B. Foley and Robert J. Marrin.

The following gentlemen compose the board of trustees David Homer Bates, James R. Beard, Thomas M. Brennan, Charles P. Bruch, Albert B. Chandler, William J. Dealy, Louis Dresdner, William B. Dunn, Lewis B. Foley, Edward P. Griffith, William Holmes, Edwin F. Howell, Walter C. Humstone, Gardner Irving, Robert J. Marrin, Michael J. O'Leary, Franklin J. Scherrer, Frederick G. Sherman, Charles A. Tinker and John B. Taltavall, New York, and George H. Usher and William C. Daviet, Atlanta, Ga.

Mr. Reid's fatherly interest in his employes when he was telegraph superintendent at different places in the early days of the telegraph is well known. When he made business visits to the various offices under his jurisdiction he always made it his duty to shake hands with the messengers and give them some words of encouragement and fatherly advice, urging them to make themselves useful and remain in the service permanently. Many telegraph officials of today state that it was largely by reason of this early advice that the operators of forty or fifty years ago were men of unusual intelligence and ability.

Invention of the Telegraph.—In a paper read recently before the Philadelphia Academy of Natural Sciences, by Mr. W. J. Holland, director of the Carnegie Museum at Pittsburgh, Pa., Dr. David Alter, of Freeport, Pa., was credited as having preceded Prof. Morse in the invention of the telegraph. Dr. Alter, said the speaker, was a physician of inquiring and ingenious mind, and invented a crude system of telegraphy independently of Morse's. Dr. Alter was most emphatic, the speaker said, "in disclaiming any credit for the introduction of the telegraphic apparatus which the genius of Morse involved."

Get-Rich-Quick Losses. — Postmaster-general Hitchcock estimates that the American public has, within the last year, been swindled out of $100,000,000 by get-rich-quick schemers, who make illegitimate use of the mail to carry on their work. He states that about $6,000,000 was obtained by the promoters of the United Wireless Telegraph Company before the post office inspectors became aware of their operations.

A New Morse Telegraph System.

J. W. LARISH, NEW YORK.

Mr. Patrick B. Delany, the well-known inventor, has devised and brought to perfection a new system of Morse telegraphy, possessing greater efficiency than the present methods. It requires one-third less labor in the manipulation of signals; it has greater "reaching" quality due to the character of the impulses, and what has long been desired in simple Morse operation, it possesses complete secrecy.

The apparatus consists of the ordinary instruments of the telegraph, and the operation is by means of the usual auto-dot or vibroplex transmitters.

The employment of polar relays makes the system practically self-adjusting, and as all the characters of the Morse code, except the letter "e", or single dots in combination with dashes, while being rendered in the usual form of dots and dashes at the sending and receiving points, really pass over the wire as dashes only, which necessarily gives them better carrying qualities over direct lines and through repeaters. The system can be operated singly or duplex, and repeatered.

While the aim of the inventor was to evolve a secret method of simple Morse operation, he discovered that he could not only do this without sacrifice in efficiency of the old methods, but that it was practicable to exceed the possibilities of the present Morse to a large degree. Actual demonstration has repeatedly shown this.

In Fig. 1, K is a transmitting key of the usual auto-dot type, each arm of which is connected with main batteries of opposite polarity. The "dash" and "dot" polar relays are joined oppositely. When the dash lever of K is moved over against L the dash relay responds to operate the

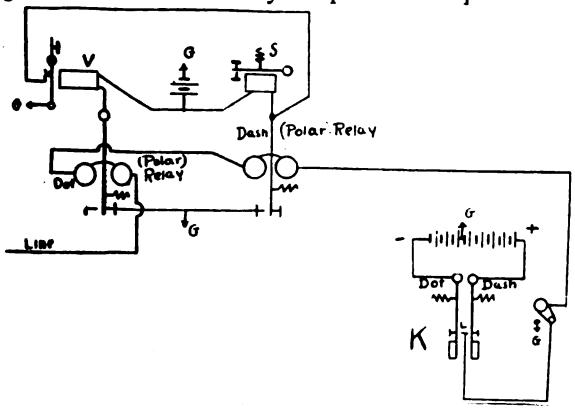

FIG. 1.—DIAGRAM OF SECRET TELEGRAPH SYSTEM.

sounder S (the dot relay remaining quiet) in accordance with the duration of the key contact at L. When the dot lever of K is connected to L the dot relay responds releasing vibrator V which then automatically makes and breaks the sounder circuit, for dots, in the usual auto-dot or vibroplex fashion (the dash relay remaining quiet), the number of dots depending upon the duration of the dot lever contact with L at K.

In both cases, with either dots or dashes, a constant current passes to line varying in duration, in the case of the dots, according to the number of impulses in the letter, and with the usual interval in the dashes. For example, the word "shipping" would pass over the main line as shown in Fig. 2, but be resolved at the receiving points, into the usual Morse characters, as shown also in Fig. 2.

A modified arrangement requires but one relay for both dots and dashes, but the sketch shown here is of simple form for description.

With a simple 3-point switch at each station, the "secret" transmission may be changed to the

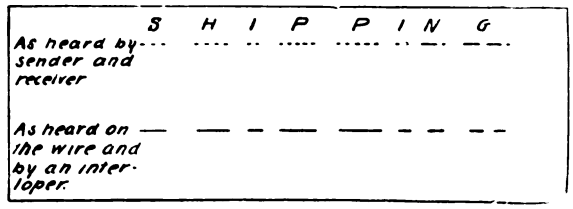

FIG. 2.—DIAGRAM SHOWING HOW MORSE CHARACTERS ARE TRANSFORMED.

usual Morse, so that two or more offices can quickly change from one to the other without considering the intermediate or other disinterested stations.

An analysis of the Morse alphabet from A to Z, shows that the total impulses are:—

	Present Method	New Method
Letters	77	52
Numerals	41	25
	118	77

which means practically one-third less movement of the hand by the Delany method.

Other features of advantage are:—

1.—The dots being made mechanically and locally are not subject to the erratic characteristics, or personal equation of the operator, nor can they be affected by the extraneous influences on the wire, such as inductive disturbances, etc., which are much more likely to attack dots than to distort the dashes, in which form they are transmitted.

2.—The fewer and longer impulses are advantageous in repeatering, and also cause less inductive interference with adjacent wires.

4.—Simplification and increased efficiency are the chief advantages of this system. Usually one of these advantages suffers more or less when it is desired to emphasize the other, but in this instance there is gain in both.

The value of secrecy in the telegraph is, of course, obvious. It is desirable in government matters; in newspaper work and for private lines, and when it can be obtained in so simple a way, there can be no question that this system will find a useful field of application.

Mechanical Stress in Lines.—The engineering experiment station of the University of Illinois, Urbana, Ill., has issued Bulletin No. 54, on the subject of "Mechanical Stresses in Transmission Lines," by A. Guell. It is a mathematical discussion of the subject.

The Majorana System of Radio-Telephony.

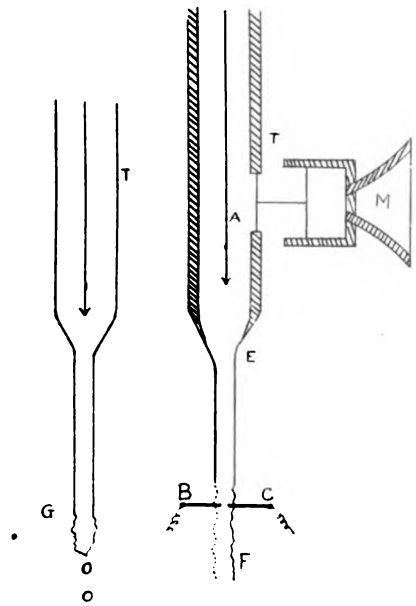
BY SAMUEL WEIN, NEW YORK.

One of the most successful systems of radio-telephony is that of Prof. Quintana Majorana, the director of the Telegraphic Institute of Rome, Italy. With his system he has been enabled to carry on a conversation between Rome and Messina, a distance of 312 miles.

The method of producing the required undamped oscillations is identical with that of the Poulsen system.

The essential features of the transmitting station consist of a peculiar method of superimposing the radiated undamped oscillations. It consists of a "liquid or hydraulic microphone," shown in Figs. 1 and 2.

At T is a tube in which there is water or another liquid flowing in the direction of the arrow. As



FIGS. 1 AND 2.—HYDRAULIC MICROPHONE.

the bottom of the tube is contracted so as to give a small opening at this point the water will come out of the bottom of the tube in a somewhat fine stream. Such a stream continues in regular smooth form for some distance below the tube, and then at G it begins to break up and falls in drops. It is found that when we give a shock or other disturbance to the main tube, this favors the breaking up of the water stream to form drops, and the shocks, especially if they are sudden and frequent, act so as to shorten the distance of the breaking point G from the tube end. The tube is also sensitive to sound vibrations, so that when a sound is made in the tube there is an action on the water stream which depends on the nature of the sound. Prof. Majorana was thus able to make the water column sensitive to the sounds of the human voice, but it was only after a considerable amount of experimenting that he succeeded in using such a device as a microphone transmitter. This he carries out in the arrangement shown in Fig. 2, his design being to make the voice act directly on the water inside the tube so as to change the pressure, and this very near the lower opening of the tube. To do this, he makes the tube of a strong and solid material, except at one part, A, where he makes an opening and places across it a thin and elastic partition. This is connected by a cross rod with a diaphragm of the usual kind belonging to the transmitter mouthpiece M. Speaking into the mouthpiece or making any kind of sound will cause the diaphragm to vibrate, and this movement is transmitted to the liquid within the tube and has an action on the stream of water. In the usual condi-

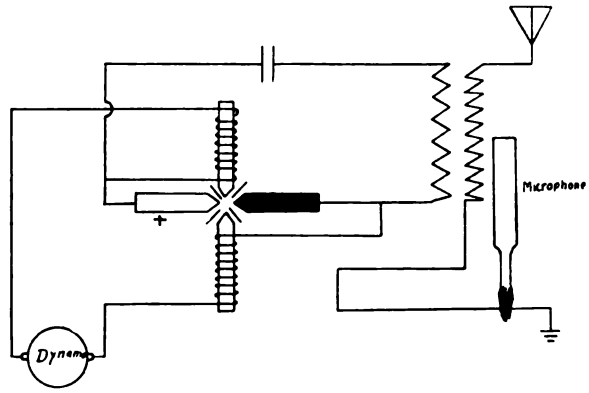


FIG. 3.—TRANSMITTING APPARATUS.

tion of the stream, when there is no sound made, there is a straight and unbroken water column from E to F, as the drops commence to form below F. However, when we make a sound of a given rate, such as a musical note, in the microphone, the water column is found to contract in a certain way, as seen in the dotted lines, and the contractions increase as we come to the lower part of the columns near F. The drops commence to form higher up in this case.

A pair of fine wires B C are inserted in the column near the lower part where the contractions are the strongest, and they are connected across

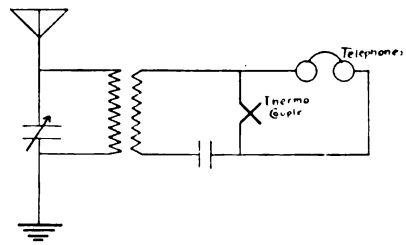

FIG. 4.—RECEIVING APPARATUS.

by the liquid. A current passing in the wires will thus depend upon the shape of the water column at this point, as when the stream is narrow, we will have a higher electrical resistance between the points than when the stream is expanded from the effect of the vibrations, as in the dotted lines. On the other hand, this action of the water is variable and depends on the kind of sound given in the microphone, so that the electrical resistance between the points depends on the sound in the transmitter.

A higher current than usual can be employed in this case, seeing that the part of the liquid which

Digitized by Google

carries the current is always renewed, so that it does not heat to any extent. Prof. Majorana is also able to regulate the conductibility of the stream by changing the nature of the liquid (acidulated or salted water, mercury, etc.), and also the diameter of the stream, and he can, furthermore, adjust the distances between the metal points as well.

The transmitting hook-up is shown in Fig. 3. There is no danger of burning or heating of the microphone.

A thermo electric couple has been used by Prof. Majorana as the detector. The receiving apparatus is shown in Fig. 4.

The writer's thanks are due to Mr. Nathan Levy for the assistance he has rendered in preparing this article.

CONSERVATION TALKS—IV.

BY P. KERR HIGGINS, OKLAHOMA CITY, OKLA.

Toll Supervision.

Lost circuit time on toll lines constitutes one of the greatest wastes the telephone company has to contend with and possibly one of the easiest to overcome. There are many complicated and expensive methods now in use to avoid such loss, but few seem to completely meet the requirements. It remains, therefore, for us, as telephone men, to pattern our supervision after telegraph practice, by using the daily log, which has for years been used by telegraph operators on important circuits.

This log of a memorandum sheet or book in which is noted all irregularities occurring during the day. This scheme was tried some years ago at exchanges in Oklahoma but was not as successful as expected due to the fact that it was not properly maintained and the plan did not go far enough. Most toll wire chiefs have been accustomed to using such a daily log to good advantage, but it remained, so far as I know, for the Southeast Missouri Telephone Company's traffic department to elaborate on the daily log and put it into such shape as would insure the best results from a telephone traffic standpoint.

The matter was suggested and adopted at a traffic conference at Sikeston, Mo., when every traffic representative present pledged himself to give it a fair and impartial trial. As a result of this conference and the adoption of this inexpensive supervision, the service was improved 100 per cent. almost immediately. At first the service and circuit logs were full of notes and memoranda, which became less every day. After one month's trial the logs have become almost clear, every operator along the line realizing and knowing that she is watched by every other operator, every chief operator working with and for one another.

The following extracts from instructions issued by the traffic manager explain in detail the working of a scheme which will bear investigation and trial by any company not now getting toll line co-operation.

Three forms are used; one a service log, one a circuit log and the other is used for communicating the notations made, to another exchange when necessary. This may be done over the wire at night or when the lines are not busy. Such communications are also used for reporting irregularities on other company lines to headquarters. The purpose of the circuit log is to keep a record of the working condition of our circuits, noting thereon irregularities of any kind affecting their working efficiency.

The circuit log is started each day at 7 a. m. and states the conditions of each circuit by number when tested. The day closes about 10 p. m. and shows the condition at that hour. If no trouble has been noticed the notation is made: "Clear all day," in addition to the other two entries. When trouble is cleared, the circuit number and time O. K. is noted. Each sheet has space for seven circuits. When a circuit is out of order it should be tested frequently to see if it is cleared.

The service log is for the purpose of recording all happenings of interest during the day affecting the toll line service, such as, 1, When an office does not give a verbal clearance on a tandem circuit; 2, Delays in answering; 3, An office refusing to give filing time; 4, Calculagraph not working well; 5, An office failing to report on calls, etc., etc., remembering to note anything which will tend to improve the toll line service whether it is an error of omission or commission.

A code is used in connection with the log to reduce writing to a minimum and chief operators revise the logs each morning, take such action as is necessary and then file them away for reference.

Mr. J. C. Smith, formerly manager of the Western Union office in Detroit, Mich., and now in other business at Toledo, Ohio, writes:

"I am a subscriber to TELEGRAPH AND TELEPHONE AGE and have been for a number of years. To me it is the most interesting publication I receive. It is full of good things and if the operator who has ambitions to improve his position and make himself of greater value to his employers would not only read your publication, but study the things and subjects it discusses, he would find that his knowledge of the practical telegraph business would grow rapidly and that, in itself, would inspire him to greater efforts. The trouble with a great many telegraph operators of today is that they allow themselves to become part of the mechanical apparatus and then find fault because they are not singled out for promotion instead of those who study the conditions, improve their minds and show themselves fit for larger responsibilities."

TELEGRAPH AND TELEPHONE AGE is the leading paper in these two fields and is progressive and newsy. Subscription price, $2 00 per year.

Wm. Slingo, Engineer-in-Chief British Postoffice, London.

Mr. William Slingo, the new engineer-in-chief of the British Postoffice, London, England, commenced his business career on the commercial side of the telegraph department of the General Postoffice, at the Central Telegraph Office, in 1870. Mr. Slingo is regarded as one of the pioneers of technical electrical education, for in 1876 he founded the Telegraph School of Science

WM. SLINGO,
Engineer-in-Chief British Postoffice, London.

at the General Postoffice, London, and remained as principal of this school until 1898, when it was closed. He was also head of the electrical section at the People's Palace, which is now known as the East London Technical College. On the close of the postoffice telegraph school Mr. Slingo's services were transferred to the engineering department of the postoffice, where he was employed in the first instance as a first class technical officer. In this capacity he established Hughes duplex working between London and the continent of Europe, and he also developed a system of accumulator working which was applied to a considerable extent to the telegraph offices in the United Kingdom. At the close of 1903, Mr. Slingo was promoted to the position of superintending engineer of the North Wales Engineering District with headquarters at Liverpool, where he acquired considerable practical experience in telegraph and telephone engineering practice. In January of last year, he returned to the General Postoffice, London, to fill the position of assistant engineer-in-chief.

His appointment to the position of engineer-in-chief dates from March 1, succeeding Major W. A. J. O'Meara, who recently resigned on account of ill health. In the first year of his postoffice service the transfer of the telegraphs to the State was accomplished; in 1889 the undertakings of the submarine telegraph companies were absorbed in the postoffice service; in 1896 the trunk long distance telephone services were transferred to the State, and at the dawn of the present year, the local telephone services, hitherto controlled by the National Telephone Company, were transferred to the postoffice.

In view of the transfer of the company's plant and staff to the State, the preparation of the inventory, the valuation of the plant and the forthcoming arbitration proceedings in connection with that valuation, it will be realised that Mr. Slingo has taken up the reins of a great department at a time of considerable public importance. Mr. Slingo's reputation as an author of technical literature is world-wide. Chief among his publications is a book on electrical engineering, the authorship of which he shared with Mr. A. Brooker. Mr. Slingo was born in London and is 56 years of age.

Retirement of Samuel Reese, an Old Timer.

Mr. Samuel Reese, manager at Cleveland, Tenn., has retired on a pension after a service of fifty-two years with the Western Union Telegraph Company, forty-three of which were spent in Cleveland. He entered the telegraph service with the East Tennessee, Virginia and Georgia Railroad and was for five years at London, Tenn.

Mr. Reese was a military telegrapher during the civil war and in 1863, '64 and '65 served in eastern Kentucky and in eastern and middle Tennessee under military superintendents, Captain

SAMUEL REESE,
of Cleveland, Tenn., an Old-Timer Just Retired.

W. L. Gross of Danville, Ky., and Captain J. C. Vanduzer of Nashville, Tenn. During the early part of his military telegraph career he was an operator in the Confederate service and was captured by the Federal troops in Tennessee, and pressed into the Federal telegraph service, remaining loyal to the cause until the end.

Appendicitis is becoming a fashionable ailment among telegraphers, no less than six operations for this disease having reached our knowledge within the past two or three weeks. It is an expensive fashion too.

Telegraph and Telephone Age

Entered as second-class matter, December 27, 1909, at the Post-Office at New York, N. Y., under the act of March 3, 1879.

Published on the 1st and 16th of every month.

TERMS OF SUBSCRIPTION.

One Copy, One Year, in the United States, Mexico, Cuba, Porto Rico and the Philippine Islands . $2.00
Canada 2.50
Other Foreign Countries 3.00

ADDRESS ALL COMMUNICATIONS TO
J. B. TALTAVALL, - - - Publisher
253 BROADWAY, NEW YORK.
T. R. TALTAVALL, Editor.
R. J. WEEKS, Manager Advertising Department.

CABLE ADDRESS: "Telegage," New York.
Telephone: 6657 Barclay

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

April 16, 1912.

Delayed Newspaper Mail.

Much annoyance is caused to subscribers to this journal, as well as all other journals, living at distant points by the delay in the receipt and delivery of their copies by the post office authorities. In his zeal to put the postal service on a profitable basis Postmaster-General Hitchcock has incommoded the reading public by requiring that newspaper mail shall be forwarded to destination by fast freight. What "fast freight" means is a question. Practically, it means that our paper is delayed in its delivery in the middle western states from nine to sixteen days. All trade papers are subject to the same delay, and much dissatisfaction is expressed over the results of the postmaster-general's ruling.

The Western Union Pension Plan.

Large business concerns are more and more realizing the justice and advantage of retiring faithful long-service employes on pension. It is justice to the employes so retired, because it provides them with a competence that will insure them a living during their remaining years of life, and it is advantageous to the employing interests because it enables them to keep younger and more active men in the service.

The Western Union Telegraph Company is the most recent of the large concerns to adopt a pension plan for the benefit of its employes. In justice to the company, however, it should be pointed out that as far as the public knowledge of the matter is concerned, it is new, but practically it is not new because the company has for many years been retiring old employes on pension. In the meantime, it has been perfecting the plan and arranging the details.

The announcement of the institution of the pension scheme was recently made in official form, and that means that the principle alone was stated. Its practical application and operation seem to be interpreted differently according to the individual attempting to interpret the provisions, but, of course, there is only one right way, and that way we have attempted to point out by means of a few examples, as printed on another page in this issue. These will enable any one interested to calculate the pension allowance under any conditions coming within the scope of the plan.

Where so many employes are concerned, as in the case of the Western Union—30,000—the problem of arranging an equitable pension scheme is not an easy one of solution in view of the large territory over which the system extends and the widely diversified occupations of the employes. But the company has dealt fairly in the matter and it hopes that this beginning will extend to further protection of the employes.

The pension budget will, of course, add a large item to the company's expense account, but what it loses in money will be largely offset by the gain in efficiency in the service. This gain will be brought about in two ways; first, by keeping younger and more active men at work, and second, by promoting that peace of mind that comes from the knowledge that they will be provided for in their old age if they are faithful in the performance of their duty toward the company.

We have received several letters expressing gratitude and appreciation on the part of managers and employes of the good feeling of President Vail and his administration toward the faithful old employes of the company, and there is no doubt of the existing sentiment in the minds of the fraternity at large that the pension plan will have a great influence in bringing the officers and employes into more harmonious relations. No one can deny that contented employes constitute the greatest and most valuable asset a company can possess, and now that the telegraph company has given abundant evidence—in the supplying of typewriters and instituting a pension scheme—that it has the welfare of its employes at heart, the employes, on their part, will naturally show their appreciation for these benefits in the form of greater ambition, loyalty and efficiency.

Wireless Treaty Ratified by United States.

The United States Senate, on April 3, ratified the International Radio-Telegraph Conference, signed at Berlin, Germany, in November, 1906. This government will therefore be represented on equal terms with the other signatory powers at the London Conference which is to be held on June 4, and ships flying the American Flag will hereafter be accorded all the rights guaranteed by the conference. The treaty has lain dormant in the pigeon-hole of the Senate Committee on Foreign Relations at Washington since 1906. It was favorably reported to the Sixtieth Congress but the session adjourned without action upon it,

Digitized by Google

and on account of the great importance of the approaching conference in London it was brought before the present congress and finally ratified.

The naval delegation from the United States will consist of Rear-Admiral John R. Edwards, U. S. N., head of the American delegation; Lieutenant-commander David W. Todd, U. S. N., and Dr. Louis W. Austin, Ph. D.

The "All-British" Cable Not Favored.

Postmaster-general of England, Hon. Herbert L. Samuel, stated in the House of Commons on April 2, after referring to the reductions in cable messages between England and America, that he did not wish to regard these reductions as final, but did not see his way to demand further reductions at present.

"Any company," he said, "coming forward to lay a cable, owned by British subjects, between Canada and the United Kingdom, either with a reduced tariff or at the rates in force, would be welcomed by the government, but it is not prepared to grant a subsidy for the formation of such a company."

The postmaster-general further stated that the government was not in favor of a state-owned cable across the Atlantic.

During a debate on April 3, Mr. Samuels stated that in order to improve strategic communication and obtain a prospect of further reduction in press and other rates, he had entered into an arrangement with the Marconi Company for the erection of a chain of wireless stations to connect this country with India, Australia, and New Zealand, at a total expense of $2,500,000.

"This plan," he said, "will place the British Empire far in advance of any country in the world in respect to wireless telegraphy. I believe that this will be of importance from a naval and military point of view, and I anticipate that it will enable rates to be reduced for wireless dispatches sent from England, and from those parts of the empire, while it will not be unremunerative to the governments who are partners in the enterprise."

In dealing with the arguments adduced in favor of a new state-owned Atlantic cable, Mr. Samuels pointed out that there could be no disclosure of strategic secrets under the present system, because the Admiralty telegrams were sent in cipher.

Mr. Samuels adhered to the position he had taken up that a state-owned Atlantic cable could only be run at a loss. It could obtain no constant aid or certain volume of Canadian business because the land lines in Canada belong to groups of companies, which were in close alliance with the cable companies, and would not give facilities to telegrams that passed across the state-owned cable. Nor, he added, could we send across the Atlantic from this side, any large volume of business because the government has a long-standing agreement with the Anglo-American Company, which expired, he believed, about 1928.

The cost of an Atlantic cable would be about $2,500,000, and he was advised that the annual cost of maintenance, including a sinking fund, would be $250,000, and the probable revenue would be about $125,000 a year. There would be a loss, therefore, of 50 per cent. on this cable, and the government saw no reason for incurring what it regarded as a certain loss in order to achieve results, which could be achieved without any risk of loss at all.

An important step had been taken, he said, in obtaining government control of cable rates in connection with the renewal of landing agreements. He did not purpose to put this control into immediate operation in view of the fact that the companies had voluntarily made such large reductions in their rates quite recently, but after some time, in which the effect of those reductions could be observed, the question would come up for consideration whether the rates for code and urgent telegrams should or should not be required to be reduced under the powers now conferred upon the postmaster-general.

In view of the fact that wireless telegraphy was making great progress, he thought, the House would be ill-advised to press upon the government this large capital expenditure with its considerable contingent annual deficit, when reduction of cable rates had already been achieved to a large extent, or could, in the future, be achieved to a still larger degree by other methods which would not involve expense.

New Book.

TELEPHONY. By Samuel G. McMeen and Kempster B. Miller. 948 pages, 671 illustrations. Chicago: American School of Correspondence. Price $4.00.

This latest addition to the literature on the telephone has a decided advantage in being the product of two men whose knowledge of and experience and reputation in telephony are unquestioned. They are both among the most active and leading telephone men of the time, and what they say regarding the art may be accepted as authoritative and up to date.

The book is designed with the care that comes from knowledge and experience, and is a complete exposition of the art of telephony, both in theory and practice. Every drawing used was especially prepared for this work, and each one has the valuable merit of being clear and distinct.

The work has fifty-three chapters, Chapter forty being devoted to telephone train dispatching. A partial list of other subjects treated of in the various chapters includes: History and development, acoustics, lines, transmitters, receivers, primary cells, electromagnets and inductive coils, condensers, selective and non-selective party-line systems, protective means, switchboards, private branch exchanges, intercommunicating systems, traffic; phantom, simplex and composite circuits, lines, cables, poles, etc., underground construction, wiring, testing, etc. From this list an idea may be gained of the scope of the work, and railroad men will be especially interested in the book by reason of the special chapter on telephone train dispatching, which describes in a general way the various systems in use.

Copies can be procured of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York, on receipt of price.

Course of Instruction in the Elements of Technical Telegraphy—XIII.

(*Copyrighted.*)

(*Continued from page 214, April 1.*)

[We began in our issue for October 16, 1911, the publication of a course of instruction in technical telegraphy. The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and is divided into chapters, following one another in logical order.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases, and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.]

Fall of Potential.

The idea of potential essentially involves a relative condition of two points, the term being used to denote the difference between the potential, or electrical condition of a body or point, and the potential of the earth, which is assumed to be zero. The potential at any point in a wire therefore represents the excess, or the defect, of its potential above or below that of the earth.

If the positive pole of the battery be to line, the potential at any point along the line will be higher than that of the earth. If the negative pole be to line, the potential at any point will be lower than that of the earth.

In the fifty-mile race, used as an illustration of Force, Resistance and Current, if the track be level, and of uniform smoothness, it is evident that the cyclist's strength will fall gradually from its full height at the start, to zero, at the finish; and,

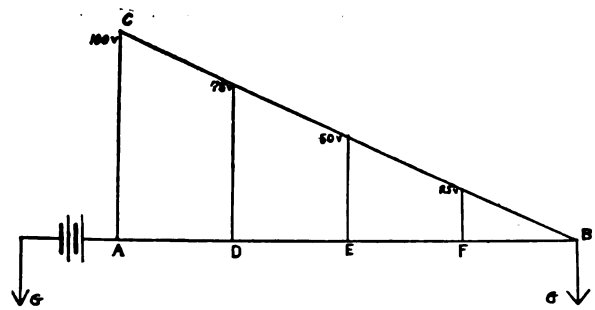

FIG. 1.—DIAGRAM ILLUSTRATING FALL OF POTENTIAL.

since his speed is uniform throughout the race, his loss of strength will be proportional to the distance he has covered. At 25 miles, or half way in the race, his strength has fallen to ½ its original value; at ¾, to ¾ its original value; and so on, until at the tape it has fallen to zero.

Similarly, in a wire of uniform resistance, the fall of potential at any point will indicate the distance between that point and the battery.

This is shown graphically in Fig. 1. Let AB represent a wire of uniform resistance, 50 miles long, and AC the potential at the point A: the slanting line CB will then represent the fall of potential along the line AB. At E the potential has fallen ½, as may be proved by measuring the height of EH as compared with AC. The point E is, therefore, the center of the wire, or 25 miles distant from the battery. At D the potential has fallen ¼; therefore AD is 12.5 miles in length.

Similarly the point F is ¾ of 50 = 37.5 miles from the battery, and the point B, where the potential has fallen to zero, is the end of the line.

If the wire be not of uniform resistance the potential at any point along the wire is proportional to the resistance overcome. If ¼ of the total resistance has been overcome, the original pressure has fallen ¼ at that point; if ½ the total resistance has been overcome, ½ the initial potential has fallen, and so on, until at the end of the line, where all the resistance has been overcome, the pressure is zero.

Example: To find the resistance overcome at a point in a circuit of 5000 ohms where the potential has fallen from 100 to 10 volts.

Solution: The potential being 10 volts there has been a fall of 100 — 10 = 90 volts up to that point. This is $\frac{90}{100} = \frac{9}{10}$ of the whole pressure, therefore $\frac{9}{10}$ of total resistance has been overcome;

$\frac{9}{10}$ of 5000 = 4500 ohms

Now if the total resistance of the circuit and the current strength be known, Ohm's law will give the initial potential, since IR = E, and since the potential falls through the circuit from its initial value to zero, E, in the equation, may be regarded as the fall of potential in the entire circuit.

The same equation IR = E holds good to find the fall of potential between two points, provided R, in the equation, represents the resistance between these two points.

It is better, however, to change the equation to IR = E, as R and E do not now represent the total pressure and total resistance. The application remains the same.

Example: To find the fall of potential in a section of wire having 200 ohms resistance, when a current of .02 ampere is flowing.

Solution: E = IR = 200 × .02 = 4 volts. Ans.

Example: To find the resistance of a section of wire through which the fall of potential is 4 volts, the current being .02 ampere.

Solution: $\frac{E}{I} = R = \frac{4}{.02} = 200$ ohms.

Example: To find the current flowing when there is a drop of potential of 4 volts through a section of wire having 200 ohms resistance.

Solution: $\frac{E}{R} = I = \frac{4}{200} = .02$ amp.

Example: A local circuit has a sounder of 4 ohms resistance and a battery consisting of 2 gravity cells. What is the fall of potential between the sounder terminals?

Digitized by Google

Solution: The internal resistance of 2 gravity cells = 4 ohms.

The external resistance = 4 ohms.

Total resistance = 8 ohms.

The current in the circuit $= \frac{E}{R} = \frac{2}{8} = .25$ amp.

The resistance between the sounder terminals is 4 ohms, therefore $E = 4 \times .25 = 1$ volt.

Solution 2: The resistance of the sounder is ½ the total circuit resistance, therefore ½ the initial potential must have fallen through it. ½ of 2 = 1 volt.

(*To be continued.*)

Habit.

BY J. W. MCMAHON, DISTRICT COMMERCIAL MANAGER, WESTERN UNION TELEGRAPH COMPANY, NEW YORK.

As we interpret the word, Habit is nothing more than the manner in which we do things; merely a custom, or, in other words, a practical routine, a method. Let a young man at the outset of his career resolve that he will, by all fair means, win a place in the world. Let him neither shrink nor shirk, but make up his mind to pay the full price. "Rest," said an eminent surgeon, "is not what I want, but strength." Moreover, to secure one's right to amusement and recreation one must pay an honest price, which is a good day's work. Life, it has been asserted, begins with renunciation and the "Angel of Martyrdom is brother to the Angel of Victory."

Success depends so largely upon the habits which are formed in early life, that nothing would seem to be more important than to have the strongest possible conviction of this fact impressed upon the mind at the very outset. The great tendency of all of us is to form habits and get into ruts. Fortunately, this tendency has its good side; if it, indeed, be true that

"Ill habits gather by unseen degrees,
As brooks make rivers, rivers run to seas."

Habit forms itself by repeated action. Habits are like the paths beaten hard by the multitude of footsteps which go to and fro. The proclivities which develop and harden into habits are likely to reveal themselves early, and, when properly encouraged, they often result in brilliant achievement. Napoleon's boyish passion for his mimic cannon foreshadowed the terrible execution of his artillery in later years.

We are unconsciously educated by our surroundings, by our associations, and by our habits of thought. The influence of our surroundings is a very potent one. All of us control, to a great extent, our own destiny. Undaunted energy and unflinching determination ever and everywhere make their impression on our lines and bring success.

Habit increases our facility for work. It is the secret of skill in all realms of human endeavor. A habit of classification is of immense value. Let one learn to have "pigeon-holes in the brain" and as facts come under our observation classify them by putting together by themselves those which are related. We easily remember that which interests us. A vivid conception of a subject, whatever it be, is that quality in a man which makes him clear-headed.

We need not fear to undertake the acquisition of any habit which seems desirable; for it can be formed, easier than one may at first suppose. The habit of improving every moment of time, for instance, is invaluable, and the inflexible rule of regularity soon becomes a controlling factor in our lives.

Let us apply a good habit to the telegraph. Rapid communication to-day is the keynote of modern science, and the telegraph is so essential to the world's activities, that it shares more or less in every achievement. What better habit can the telegraph fraternity form than to uplift and praise the economic value of the service and exemplify the habits that tend to secure the respect and admiration we are entitled to. We have every means to form such habits and the power to apply them industriously and thus gain the victory.

Telegraphers of Today.

An excellent opportunity is offered to telegraph people in general to become acquainted with over 600 prominent telegraph officials and others identified with the telegraph, the railroad, the submarine cable and press associations of the past generation, through their portraits and sketches of their careers as published in "Telegraphers of Today."

This work was issued in 1894 and includes biographical sketches of all the individuals connected with the interests mentioned at that period, many of whom have passed away from their earthly labors. The younger generation, however, will find much of interest in looking upon their portraits and reading of their achievements in life. Many of them are still alive and in harness in the telegraph and other fields of activity.

Mr. J. J. Ghegan, president of J. H. Bunnell & Co., New York, who recently received a copy, expresses his appreciation of the work as follows: "Copy of 'Telegraphers of Today' received. I casually saw a copy of the book when first published, but never had I an idea that it was so beautiful, interesting and historically accurate. It should be of great interest to telegraphers with any sentiment in their makeup. It is magnificent, unique, and I truly pity those of the fraternity who fail to secure a copy before the edition is exhausted."

This book, which is 11½ x 14 inches in size, was originally published at $5 per copy, but in order to close out the remaining copies we offer them at $1 per copy by express, charges collect.

Send orders to TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Mr. F. E. Howell, manager of the Western Union Telegraph Company at Utica, N. Y., writes: "Here is $2.00 to make me good for another year. Wish to thank you for continuing my subscription. If your readers keep up with the AGE, they are all top notchers."

Digitized by Google

Western Union Pension Plan.

President Theo. N. Vail, of the Western Union Telegraph Company, on March 28, announced the institution of a pension scheme for the benefit of the 30,000 employes of the company. The plan in detail, showing allowances, is as follows:

After twenty years of service and up to and including the twenty-fifth year of such service one per cent. of the average salary for the ten years immediately preceding retirement, multiplied by the total years of service.

After twenty-five years of service and up to and including the thirty-fifth year of such service one and one-half per cent. additional for each additional year.

After thirty-five years of service and up to and including the fortieth year of such service two per cent. additional for each additional year.

After forty years of service fifty per cent.

The minimum pension allowance to be $25.00 per month except when otherwise directed.

No pension under this plan to exceed $100.00 per month.

In making the announcement, President Vail said: "A pension committee has been compiling statistics and analyzing existing pension plans for many months, and while the plan which we are inaugurating does not go as far as we would like to have it, still it is a beginning, and we believe will materially assist in caring for those employes, qualified through length of service, who, because of incapacity or disability are compelled to discontinue active work.

"The solution of the problem," he continues, "has not been an easy one, in view of the large number of employes, their widely diversified occupations, and the large territory over which the system extends, together with the heavy expense to the company incident to the inauguration of the pension.

"However, it is my firm belief that all employes, identified by years of faithful service, are entitled to some financial protection against the necessity of retirement, and it is the hope of the company that this beginning will extend to a further protection of employes. Meanwhile, the inauguration of a pension plan marks an expression of appreciation on the part of the company of the loyal and efficient service rendered by its employes."

It may not be generally known, but the company before making this official announcement had already placed 250 of its employes on the pension list. In connection with the plan, the question has been asked, "What would be the effect on an employe's right to a pension if, after working continuously through any of the periods specified, he should resign, in good standing, and afterwards return to the service?"

In such a case, we are informed, his rights would not be forfeited, provided he returned to the service within one year after the date of his resignation.

We give some concrete examples of how pensions are calculated on the basis of the plan outlined.

Assume the case of an employe who has been in the service twenty years, and whose wages for the ten years preceding his retirement, have averaged $75.00 per month.

He is entitled to one per cent. of his monthly wage for each year of service. One per cent. of $75.00 is 75 cents, which, multiplied by his term of service (twenty years), gives $15.00 per month. As $25.00 is the minimum pension, this man will receive $25.00 per month instead of $15.00.

By the same method of calculation it is shown that a man receiving a salary averaging $125.00 per month for ten years, will receive a pension of $25.00 per month after twenty years' service, and one averaging $150.00 per month for the same length of time, will receive $30.00 per month.

Next, take the case of a man who is retired after a service of thirty years, and having received an average salary of $100.00 per month. He is entitled, according to the first clause, to one per cent. of the average salary for the ten years immediately preceding retirement, multiplied by the total years of service up to twenty-five, and, according to the second clause, to an additional one and one-half per cent. of the average salary for each additional year over twenty-five. For example: The average annual salary for the preceding ten years, $1,200.00. One per cent of $1,200.00 is $12.00, and this multiplied by 25 (years of service) gives $300.00 per year, or $25.00 per month. To this add, as provided for by the second clause, one and one-half per cent. of the annual salary ($1,200.00), which is $18.00 per year, and there being five years over twenty-five, the amount to be added to the $300.00 is $18 \times 5 = \$90.00$, making the total $390.00 per year, or $32.50 per month.

In the case of a man who has been in the service between thirty-five and forty years, the allowance, in addition to one per cent. of the average salary for ten years, is two per cent. for each year after the thirty-fifth. Thus the employe who has received an average of $1,200.00 a year for ten years, will receive $24.00 a year ($2.00 per month) for each year after the thirty-fifth, making the sum $444.00 per year, or $37.00 per month for thirty-six years. For thirty-seven years the amount will be $39.00 per month, and for the fortieth year he will receive $45.00 per month.

The man who has received a like salary for over forty years, will be entitled to fifty per cent. of his average salary, which will be $60.00 per month.

Belgian Telegraph and Telephone Service.—Various improvements have lately been introduced into the Belgian telegraph and telephone service, and the Belgian Administration intends to make proposals to Germany, France, Holland and Great Britain for the institution of cheaper international telephone rates.

Purified Politics.—In one of the Western states according to a newspaper, it is pointed out that during a recent political campaign no contributions were received from telegraph, telephone, railroad or brewing companies.

Induction, its Origin and Subjugation by Derived Law.

BY FRANK FISHER, NEW YORK.

Two articles on the subject of induction appeared in the issue of TELEGRAPH AND TELEPHONE AGE March 16. The article by Mr. W. H. Jones prefaced "Opportunities Always Waiting" appeals significantly to me as the patentee of a device for absorbing all inductive forces, such forces being recognized as "an inconstant quantity," and thus disturbing magnetic fields operated by constant values of electrical energy, the more delicate the magnetic field the greater the disturbing effect of the inductive forces. It is obvious that where a line or cable is operated by telephone, a Thomson recorder, or mirror, such delicate magnetic fields would be more powerfully agitated than the less sensitive fields operated by the Morse system.

On long cables where the Thomson recorder is operated, a shunt circuit is used and when the induced currents become powerful the coil is so far shunted to reduce the induction that very little of the line current passes through the coil. Such a condition frequently arises, and in numerous instances duplex working has to be abandoned, signals becoming unrecordable.

As Mr. Jones so truly writes, referring to the futility of past and present electricians to discover a "remedy for the harmful effects of induction," induction is, and has been, the bane of cable working, to my own personal knowledge for the past forty years.

However meritorious the numerous patents granted to such well-known electrical men as Athearn, Trowbridge, Kitsee, Blakeney, Gardanier, D'Humy and others, claiming to overcome, or govern inductive forces, none has absolutely accomplished it—the force still remained the master of the electrical expert. until May, 1911.

The basis of their investigations was wrong. It seemed to have become a fixed idea that nullification or compensation had to be set up to oppose these forces. Absorption never seemed to have occurred to them, and they overlooked the fundamental laws which are responsible for induced forces, namely evaporation and condensation, whose respective actions alternate atmospheric conditions which generate induced forces. The power, magnitude and universality of these forces have long been known to us through the Law of Potential.

Potential means something more or less vague to the student, but to the experienced electrician, a difference of potential means a war, between positive and negative electricity, arguing their respective rights or powers until agreed upon by the "derived law of absorption," which brings plus and minus into close embrace, and become one, quiescent. With all respect to other inventors and inventions I claim originality for the discovery of this derived law of electrical absorption, and its practical utility and, after a series of experiments, demonstrated its truth. I believe my study of these laws and long practical experience has taught me, that all inductive-magnetic field-disturbances are due to the difference of potential between the line and the earth. The potential of the lines in space varies. [Every wire chief knows that a clear sky means no inductive trouble, no loss.] At times it will vary, perhaps in clear, fine weather from 300 to 400 volts. Imagine that difference per foot with a strong wind during the prevalence of a fog or sleet storm; it is nearly beyond comprehension.

As the electrician of a cable ship a knowledge of difference of potential was exceedingly useful, especially when having to splice in from five to twenty knots from ship to buoyed end of cable. The piece had to be electrically perfect. The easiest, quickest and best way to determine this was by difference of potential, running 100 volts through the piece when in the tanks and noting the deflection. If the positive and negative deflections were the same, it meant perfect insulation and the piece was ready for splicing-in. Should the deflections differ, negative being greater than positive, it meant a fall of potential somewhere by the evolution of a gas. This method of testing occupies only a few moments, but they are precious moments at sea. It, however, proves the law "where the potential is the same there can be no induction."

In laying long sections of cable, a system for a continuous insulation test from ship to shore during submersion has been in use for years. I was in charge of the shore end arrangements of all the cables laid by the French Company from Cuba to Brazil. We used this system which proved very effective and was certainly very convenient, as I was in touch with the ship, through condenser, and dead beat mirror. The system is most simple. The shore end is joined to one plate of a condenser, thus being perfectly insulated. The other plate being joined to the coil of a dead beat mirror, and to earth. Each change of polarity which took place aboard every fifteen minutes was noted by me on the mirror, its magnetic field being altered by the impulse from the condenser by induction. Whenever the ship desired to speak to shore they simply connected in circuit the ordinary sending key. Appreciating the value of such a perfect arrangement, some years later, when induction proved so fatal to duplex cable working I conceived the idea by reversing the intensity field and condenser and creating a leak in any conductor by a tap connection. This brought the intensity field to the same potential (+) as the conductor without in any way altering the resistance of the line, because whatever voltage was used for operating the line had no outlet through this leak, as one end of the coil was insulated. The coil, therefore, would take the same potential as the line, up to the point of insulation and when joined to the condenser would remain so.

Digitized by Google

The action of the condenser convinced me that by connecting it to earth, the potential of which is (—), brought the line and earth to the same potential when induction ceases, thus placing the line coil in a neutral sphere.

Anticipating its value I forthwith took out letters patent in the United States, France, England, Canada and Newfoundland, and patents are now pending in Germany.

In the accompanying diagram I merely show where, and how the device is inserted. G is the magnetic field of whatever system may be

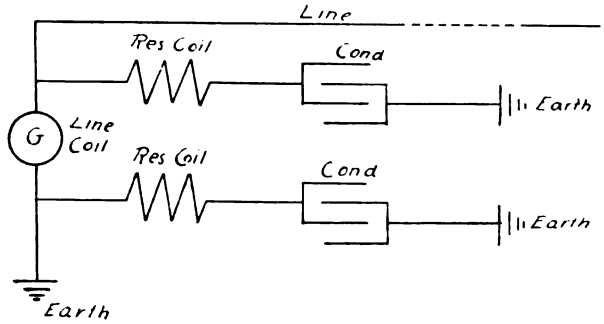

DIAGRAM SHOWING METHOD OF PROTECTING DELICATE INSTRUMENTS AGAINST INDUCTIVE EFFECTS.

worked, as the device is applicable to any and every system, siphon recorder mirror, telephone, Morse, etc., irrespective of their delicate magnetic fields. Its exceeding simplicity is its chief recommendation.

The most valuable feature of my device is its absolute constancy in duplex working. A submarine cable has two fixed quantities—resistance and capacity—they do not vary. The artificial line is based upon the ohm and farad. Why should they not become as fixed as the cable, and not subject to continual variation by atmospheric changes or local high voltage lines? I have every reason to know that my device brings the artificial line to exactly the same fixed condition as the cable or aerial and when once the apparatus is adjusted, after its initial charge, it remains fixed and constant until the cable severs. I see no reason why New York and London should not work from their respective centres direct, through a relay protected by this device.

I emphatically reiterate this opinion which is worthy mature consideration as being held by a man so closely associated with cable working for over forty years and thoroughly conversant with every phase of its ramifications, especially from the technical and dividend point of view.

Mr. Robert Morrell, general superintendent of the West Indies and Panama Telegraph Company, St. Thomas, D. W. I., writes: TELEGRAPH AND TELEPHONE AGE is so useful and necessary that I should be like a fish out of water without it. It certainly should be most useful to all telegraphers."

Report of the New York Telephone Company.

The report of the New York Telephone Company for the year ending December 31, 1911, shows the following results:

Total telephone revenue	$39,189,965.93
Total telephone expenses	29,013,188.40
Net telephone earnings	$10,176,777.53
Dividends and interest earnings	$5,043,706.82
Miscellaneous earnings	2,535.90
Total net earnings	$15,223,020.25
Deduct interest charges	$2,395,826.03
Dividends	10,000,000.00
	$12,395,826.03
Balance to surplus account and reserve for contingencies	$2,827,194.22

The combined operations of the company and its associated companies cover the States of New York, Pennsylvania, New Jersey, Delaware, Maryland, the District of Columbia, and parts of Connecticut, Virginia, West Virginia and Ohio. The following statements show the combined operating results for the company and its associated companies during 1911 (not including local connecting companies) with inter-company items eliminated:

Telephone earnings	$59,019,410.71
Telephone expenses	43,946,709.71
Net telephone earnings	$15,072,701.00
Other income	1,443,594.54
Total net earnings	$16,516,295.54
Interest charges	2,585,766.16
Balance	$13,930,529.38
Dividends declared	10,010,493.50
Balance to surplus accounts and reserves for contingencies	$3,920,035.88

On December 31, 1911, there were 888,335 stations in the system directly operated by the company and its local connecting companies, an increase during the year of 100,771. Including the associated and connecting companies, there were in service in the whole system at the end of the year 1,524,024 stations, an increase during the year of 160,254 stations.

The report is signed by Mr. U. N. Bethell, president.

To Amend the Patent Law.—A bill has been introduced in the House of Representatives at Washington to amend features of the patent law upheld by the United States Supreme Court in its recent "patent monopoly" decision. The purpose of the measure is to prevent abuse of the patent law.

TELEGRAPH AND TELEPHONE AGE is the oldest and most ably-conducted telegraph journal in America and should be read by every one engaged in telegraphy. Subscription price, $2 per year.

Testing on Railroad Telephone Circuits.

BY K. W. ENDRES, NEW YORK.

(Continued from page 226, April 1.)

PATCHING.

Before taking up in detail the methods of testing on train dispatching circuits, it is necessary to describe at some length the proper method of constructing such lines so that they can be made available for patching when desired. This is an important feature of a railroad telephone testing outfit. Means must always be provided for patching one circuit to another, for using a section of one circuit here, of another further on; briefly, the system must be flexible. A dispatcher should also be able to place trouble with some degree of accuracy so that he can send out a man to clear it. He should be able to make measurements of resistance, voltage drop or other simple tests upon the line, and how this can be done will be taken up later. As far as he is concerned personally, however, this is not considered so important as the patching feature, since the dispatcher's sole object is to keep his line working, and his first duty is to patch around a break or a ground, rather than to attempt to locate it closely on the line.

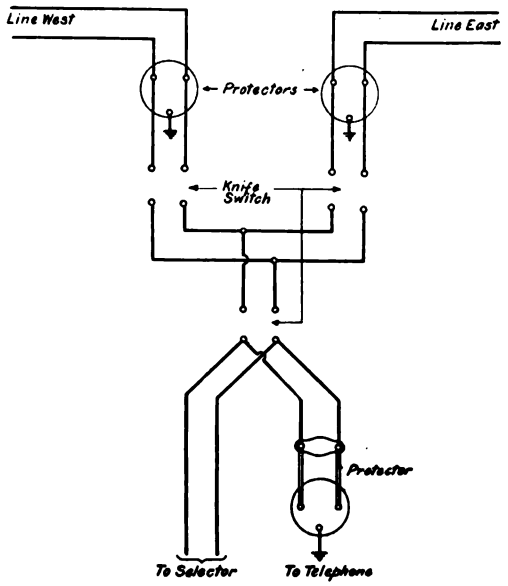

FIG. 1.—WESTERN ELECTRIC SYSTEM OF WIRING SINGLE TRAIN DISPATCHING CIRCUIT THROUGH WAY STATION.

Some train dispatching lines consist merely of the one circuit, and have no provision made for relief in cases of emergency. This is generally because there is only the one circuit available.

If, however, telegraph circuits parallel the telephone line, it is a wise plan to arrange at least two of these so that they can be used for patching purposes in times of trouble. While it would be impossible to obtain satisfactory transmission over the iron telegraph wire for any great distance, yet when used on short stretches here and there to bridge around breaks, they would operate very successfully and enable service to be maintained—the result always to be aimed for.

SINGLE CIRCUIT.

Where only one circuit, however, is installed, it is generally sufficient to wire this through knife switches at each way-station as shown in Fig. 1.

The two upper switches enable the line to be cut through or opened at each station. The lower switch connects the way-station apparatus, selector, telephone set, etc., to the line. The dispatcher can, with this arrangement, locate trouble to the nearest station. This, in general, is as close as can ordinarily be obtained in dispatching service and it has been found to be sufficient. Where a line is permanently equipped with a large amount of bridged apparatus, as in this case, accurate tests are almost impossible although instrument readings give fairly close results after a man becomes familiar with his circuit.

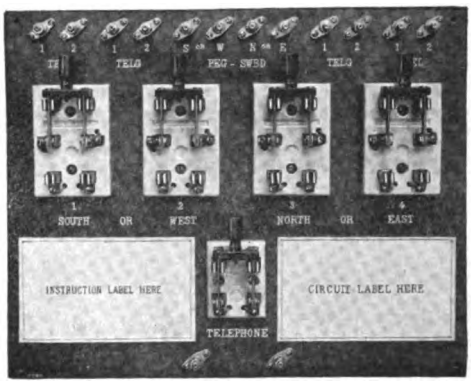

FIG. 2.—SWITCHING PANEL.

Experience has shown that testing devices on the line should enable the dispatcher or wire chief to find out readily what section must be patched, and then permit him to accomplish that patching by orders given to the proper way-station operators. After this has been done, and the line is in workable shape, he can send out his linemen to locate the trouble and restore the circuit to its normal condition.

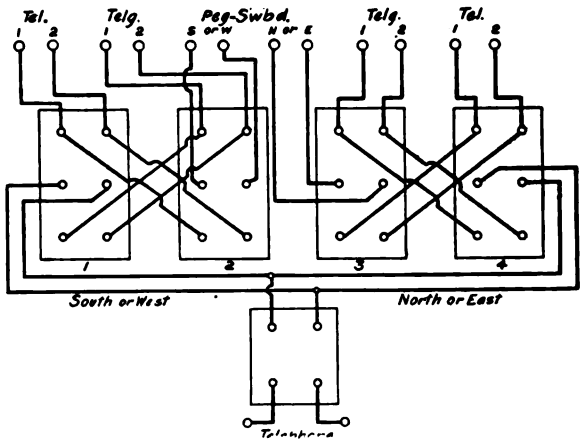

FIG. 3.—WIRING OF SWITCHING PANEL.

Digitized by Google

SWITCHING PANEL.

Fig. 2 shows a standard form of switching panel used on a number of railroads in this country where a telephone train dispatching circuit is equipped and two telegraph wires are transposed and made available for patching purposes, as outlined. The switches permit the telegraph lines which are normally cut directly through to the peg switchboard, to be used for making patches in the telephone circuit when necessary. The circuit arrangement is shown in Fig. 3 and the method of using this panel will be self-evident from this.

TEST BOARD.

Fig. 4 shows a standard form of test board which has been developed by the Western Electric Company to meet the needs of railroads for this type of apparatus on their dispatching circuits. It is a wooden box equipped with telephone jacks, cords, plugs and keys, and with it all

FIG. 4.—TEST BOARD.

the ordinary simple tests and patches incident to a line of this character can be made easily and simply. The box may be equipped with any amount of the apparatus desired, but the wiring for the complete equipment is installed initially and the addition of jacks or keys, therefore, at a later date, merely means installing these in the box and connecting them to wires already in place. The workmanship throughout is solid, substantial and neat, and the color scheme of wiring employed, together with the plain numbering of all jacks and connections, enable the circuits to be easily traced out.

DESCRIPTION OF TEST BOARD.

It will be seen from Fig. 4 and from the wiring diagram, (Fig. 5), that the test board has a capacity for sixteen jacks in parallel rows of eight each, and also a grounding jack in the centre at the bottom. Two keys are also provided in the lower part of the board. Designation strips are mounted alongside each row of jacks in order that the marking of the lines may be clearly before the operator and maintenance man. It is of particular importance on all telephone equipments where there are a large number of connections that everything should be clearly and accurately labelled for convenience in making tests and clearing trouble.

CIRCUITS.

Fig. 5 shows the circuit diagram of this test board. The outside wires are brought into protectors and from these, in turn, are carried to the screw terminal punchings numbered from one to sixteen in the diagram. These, likewise, are connected directly to the jacks. Each jack consists of three parts—tip conductor, sleeve conductor (so-called from the fact that they make contact with tip and sleeve of the plug), and an inside contact which is broken when a plug is inserted

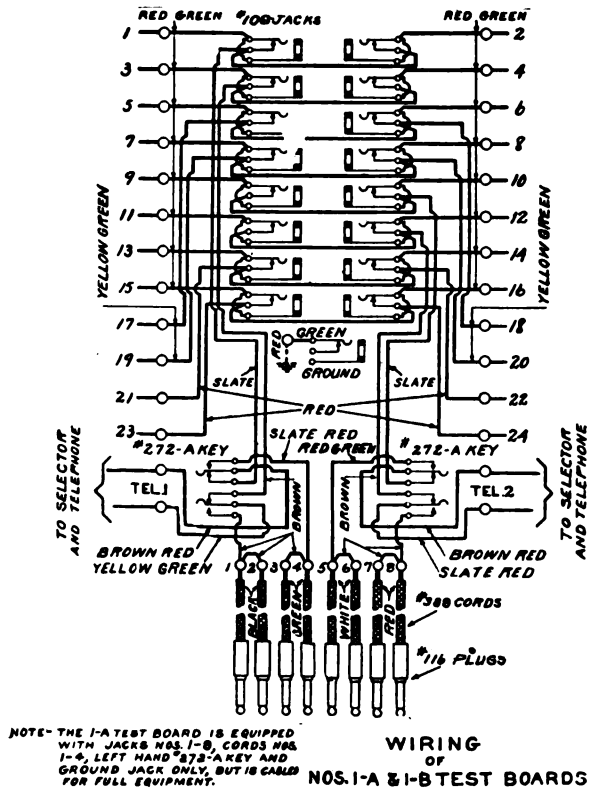

FIG. 5.—DIAGRAM OF TEST BOARD WIRING.

in the jack. These are shown diagramatically in a conventional way. In this test board, single conductor plugs are employed having their tips and sleeves in one solid piece of brass, hence the tips and sleeves of the jacks are also connected. It is necessary that the sleeves of the jack be equipped, whether used or not, in order to give the jack the requisite mechanical strength and to center the plug properly when it is inserted.

The lines come into the tip springs of the jacks (one wire per jack) on one side and are connected through their inside contacts to the corresponding springs of the jacks opposite, going out again on the line. The line or lines thus run straight through the office without break or interruption.

Selector and telephone apparatus is bridged across two of the circuits (usually the train and

Digitized by Google

message wires), from jacks 1 and 3 and 10 and 12. This connection is taken, in each case, from the inside contact of the jack. From here the two wires run to the inside contacts of the key and from the movable springs of this key to the apparatus itself. The key, in its normal "off" position is connected to the inside contacts as shown. The outside contacts of the key are connected to the single conductor cords 1 and 4 as shown. The wiring of jacks 10 and 12 on the other side of the box corresponds with that for 1 and 3 in every particular.

TELEGRAPH CIRCUITS.

It will be noticed that connections from the inside contacts of jacks 5 and 7 and 6 and 8 are also brought out to lugs 17, 19, 18 and 20 respectively. These are for looping telegraph lines through this test board before running them to the telegraph peg switchboard, and also enable patches to be made with telegraph lines. When telegraph lines are connected into this board at these points, the straps between jacks 5 and 6 and 7 and 8 should be cut. Then the telegraph peg board takes their place, through telegraph connections being made there.

OPERATION.

Assuming trouble on the train wire, the dispatcher has successive stations in turn open the train wire circuits by inserting any two plugs (attached to cords of different colors) in jacks 2 and 4 at each station. When he reaches a point beyond which he cannot signal or talk, it is a good indication of a break in the line between that test point and the next. The dispatcher then arranges to patch with the message circuit between these points. He calls the last available point on the train wire and instructs the operator there to insert plugs 1, 2, 3 and 4 in jacks 1, 10, 3 and 12 respectively and to throw the train wire key to the "on" position. This has connected the lines coming in on jacks 1 and 3 to the lines going out on the lines 10 and 12 and has broken the connection between jacks 1 and 2 and 3 and 4. It has also broken connection between jacks 9 and 10 and 11 and 12. Throwing the key has bridged the train wire operator's selector and telephone set across the cords 1 and 4 and taken it off jacks 1 and 3 which are now open and not connected to this apparatus. The first part of the patch from the train wire to the message wire is complete, and the operator is connected across the patched circuit.

The dispatcher now calls the next point beyond the break over a telegraph wire, by commercial telephone, or in any other way available. His instructions here are very similar. This operator connects the message to the train wire by inserting plugs 5, 6, 7, and 8 in jacks 9, 2, 11 and 4 respectively, and throwing the message circuit key "on." This connects his apparatus across the patched circuit likewise. Plugs 1, 2, 3 and 4 and the train wire key could have been used in this office in the same way, if desired.

If the dispatcher or a test man is making instrument readings on the line, he may wish to open or ground either side of it, and he may desire to short-circuit the line, making a loop. As already noted, inserting any plug into a jack opens the line connected to the latter. A wire is grounded by inserting one plug in the jack to which that wire is connected and the plug attached to the other cord of similar color into the ground jack. A line is short-circuited by inserting the plug attached to cords of the same color into the two jacks of that line.

(*To be Continued*)

Employes Longest in the Telegraph Service.

Whenever a Western Union employe is retired on a pension, the local press proclaims him the oldest employe with the company. In this connection it will be of interest to give the names and addresses of a few of the employes longest in the business; as shown by the records of the company, together with the years of their entry into the service.

1854—J. W. Lewis, New York.

1855—H. C. Fardon, New York, and Ziba Nickerson, Chatham, Mass.

1856—P. H. Shaughness, New York.

1857—J. H. Purnell, Opelika, Ala., W. L. Ives, New York, and A. G. Hoyt, Halifax, N. S.

1858—B. S. Black, North Sydney, N. S., G. E. Baker, New York, R. Power, New York, Z. P. Hotchkiss, Chicago, Ill., and P. H. Fall, Houston, Tex.

1859—J. H. Russell, New York.

Valuable Electrical Books.

Vest Pocket Electrical Dictionary. A practical hand book of reference containing definitions of electrical terms and phrases in use in every branch of electrical science. It is especially valuable to telegraphers and telephonists, and will be found a great aid in understanding electrical apparatus and applications of electricity in general. Price 50 cents per copy.

"Modern American Telephony in All Its Branches," edited by Arthur Bessey Smith. A very complete and up-to-date work on the subject of telephony. It has over 800 pages and nearly 600 illustrations. Price, $2.00 per copy.

Electrician's Operating and Testing Manual. By H. C. Hortsman and V. H. Tousley.

This work gives practical instructions for the management, operation and testing of the more important electrical devices now in use. It deals principally with electrical machinery and apparatus and contains much information of general value to the student of telegraphy and telephony. It is free from higher mathematics and is written in plain, easily-understood language. Liberally illustrated and substantially bound in flexible leather. Price $1.50 per copy.

These books and any others on electrical and kindred subjects, published in America or in foreign countries, may be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Ocean Cable Work.

In our issue for March 16 note was made of an address in Boston on March 1 on "Electrical Communication," by Dr. A. E. Kennelly, professor of Electrical Engineering at Harvard University, Cambridge, Mass.

Dr. Kennelly, who was formerly a telegrapher, has had a wide experience in submarine cable work and in his address he dwelt particularly upon this phase of electrical work, also on wireless transmission.

He briefly reviewed the early days of ocean cable service, which have led to a development capable of reaching from the earth to the moon, assuming that all existing cables were laid out in a straight line. Fifteen ships are now regularly engaged in maintenance work on the world's cable systems, and experience shows no sign of depreciation in cables laid in sea water. Mechanical injuries attributed to the movement of water currents of varying temperature across cables resting on rocky beds, the attrition from waves and damage done by animal life are the chief sources of wear and tear. The cost of a modern cable laid and ready for service is about $1,000 per mile, each of the later transatlantic lines representing an investment of about $3,000,000. The latter are heavily loaded with traffic and are likely to remain so for many years.

Dr. Kennelly said that thus far wireless telegraphy has brought the cable companies far more business than it has taken from them and that there is no immediate prospect of the cessation of cable laying, although wireless communication probably will monopolize the field in time.

The speaker touched upon the effects of weather conditions upon wireless transmission, emphasizing the adverse influence of solar rays upon distance of effective service. The sun appears to act like an evil eye so far as the wireless man is concerned, but it is certain that the world will learn far more about the conditions of the upper atmosphere than it would had such difficulties never arisen. The effect of intervening masses of land in cutting off signals was outlined, and the speaker stated that in entering the Bay of Genoa the Alps seem to interpose an insuperable barrier to the reception of signals from the north. Two hundred miles out at sea the messages may again be picked up, showing that in some manner the ether waves pass around the mountain ranges.

Dr. Kennelly said that in his opinion wireless communication holds the greatest possibilities for the future. Already the operator on an ocean liner possesses an electric arm capable of sweeping 120,000 square miles of sea, an invasion of space far exceeding anything accomplished in the past. In wireless telephony the prospect is bright, although the present range of communication is only about 200 miles. The present limit of cable telephony is about sixty miles, with prospects of a substantial increase by the Pupin method. A great advantage of wireless telephony is that if the receiver can detect anything at all he can hear the message clearly. Good work is being done along the lines of directing wireless waves and eliminating interference, and it is reasonable to expect progress in converting sound waves into electric waves of high power. Inter-individual wireless communication is also a possibility of the future.

A. A. Zion.

Mr. Alonzo A. Zion, superintendent of the Indianapolis Union Railway and Belt Railroad, Indianapolis, Ind., is an old-time and military telegrapher, and is chairman of the legislative committee of the Society of the United States Military Telegraph Corps. He was born in Lebanon, Ind., on July 23, 1846, and entered the telegraph service in 1859 as operator on the Lafayette and Indianapolis Railroad at Lebanon, which position he held until 1863. He was in the military

A. A. ZION,
of Indianapolis, Ind., Old-Timer and Military Telegrapher.

telegraph service from 1864 to 1865 and in 1866 he returned to Lebanon where he became agent and operator for the road on which he was first engaged, remaining there until 1873.

From 1874 to 1876 he was freight agent for the Cincinnati, Indianapolis, St. Louis and Chicago Railway at Indianapolis and in 1877 became chief train dispatcher for the Union Railroad Transfer and Stock Yard Company at the same point. In 1883 he was appointed master of transportation on the Indianapolis Belt Railroad and in 1894 was advanced to the position of superintendent of that line and of the Indianapolis Union Railway, which position he still holds.

Mr. Zion is an indefatigable worker in behalf of the military telegraph pension bills now before congress, and has exerted a great deal of influence upon the congressional committees having the bills in charge and there is now every indication of a successful issue, at this congress, of the agitation for government pensions for the telegraph operators who served in the civil war.

Selective Intercommunicating Telephone.

A selective telephone device for party lines has been recently patented by F. E. Granger, Aberdeen, S. D. It is particularly adapted to farmers' lines. It does away with the magneto signal bell and thereby eliminates the annoyance of the continual ringing of the telephone where many subscribers are on the line. It is entirely selective and secretive. A current from a battery is on the line all the time as in the telegraph system, the relay magnets at each station being connected in series on the line. The apparatus at each station is composed of a selector, transmitter and a dial showing the numbers of all the stations on the wire. Each station has an open circuit battery of sufficient power to operate the selector and this local circuit is closed and opened by the operation of the relay magnet on the line. When any one of the transmitters is operated it opens and closes the line circuit the same as does a telegraph key and all the selectors work simultaneously, with their dials. When the circuit is not in use all the telephones are disconnected from the line and their receiver-arms locked, so that removing the receiver does not connect the telephone to the line.

When a subscriber desires to call, he first puts his telephone on the line by placing the pin at the point in the wheel of the transmitter opposite his own number and swings the wheel around to the stopping point. The impulses will now advance all the selectors and dials on the line and stop at the caller's number. This will ring the caller's bell and unlock his receiver-arm. He then takes off his receiver and he is now connected with the line. Then he inserts the pin opposite the number of the party he wishes to call and swings the transmitter around to the stopping point again, and when the selectors have stopped a second time, the other party's bell is rung and his receiver-arm unlocked. This connects the two parties with the line, all others remaining cut off and cannot listen or cut in by the removal of their receivers. It is therefore a lockout system to that extent, although a third party is able to get on the line, but in order to do so he will have to throw the dials around to his own number first and the parties using the line will immediately see that he has come in and know who he is by his number.

This method is claimed to be superior to a central office lockout control because there is no central, and when disputes arise about the use of the line by two or more subscribers at the same time, it may be settled between themselves at that time. It is absolutely secretive because no one can cut in on the line without his number showing on all the dials that he has done so.

The selector is a simple mechanical device consisting of a ratchet wheel carrying a small cog wheel, which winds up just before the ratchet wheel arrives at its stopping point, and at that point is released slowly and does the work of ringing and unlocking. It releases slowly so that it may get by the operative point, when not stopped there, without doing the work. Each selector while in motion does nothing; it is only when it stops at a given number that it will ring and unlock the receiver-arm. There is no return to zero as in other automatic selecting signal devices; the dials always have a forward movement.

The talking circuit is on the same wire, but is bridged across the relay magnets through condensers. In the same way the line current runs through induction coils at both ends of the line so that the talking circuit is strictly confined within the limits of the length of the line; also the line current is, by means of condensers, prevented from going through the telephones. The system can therefore be operated with one wire and ground return.

Handling Messenger Boys.

BY E. A. RIPPEY, MANAGER WESTERN UNION TELEGRAPH COMPANY, SPRINGFIELD, MO.

This office has adopted a new method of handling messenger boys. Chair space is provided for them next to the delivery clerk, and when one boy goes out on delivery the others move up one chair, each one thus taking his turn as next out.

The messenger service has been placed on the piece basis and has proven satisfactory, delays having been reduced sixty to seventy per cent. If a messenger cannot earn on the piece plan the amount he was formerly paid on the salary basis he is dismissed and a more energetic boy put in his place.

Mario Mendez, Director-General Mexican Telegraphs.

Mr. Mario Mendez, director-general of federal telegraphs, City of Mexico, Mexico, was born in Montemorelos, Nuevo León, Mexico, March 19. 1868. He entered the telegraph service as a student in Matamoros, State of Tamaulipas, on March 25, 1885, and soon became a junior operator. From Matamoros he moved to San Luis Potosi where he became assistant chief, and in 1897 was appointed to the grade of superintendent of the first class and placed in charge of the Fourteenth Division. The Mexican war department afterward gave him a confidential commission to construct a strategic line from Chemax to Puerto Morelos, in the State of Yucatan. On the completion of this work he was congratulated by the war department for the excellent manner in which it was carried out.

He was then appointed chief of the construction department, and later became superintendent of the Second Division.

His appointment as general superintendent soon followed and he was later advanced to the position of chief of the Mexico office and finally, on January 4, this year, was elevated to the highest post in the service, that of director general of federal telegraphs.

Digitized by Google

Radio-Telegraphy.

Women Wireless Operators.—It is stated in a Seattle despatch that women wireless operators are to supplant men on steamers in the North Pacific trade, because men "are not always satisfactory."

Wireless Tower Destroyed.—The 656-foot steel tower of the wireless station at Nauen, Germany, was demolished by a heavy storm on March 30. The tower had been recently doubled in height and with a new plant it was expected that communication would be made with stations in America.

Wireless Telegraphy.—Recently an operator on board the steamer *Mantua*, off Melbourne, Australia, clearly read signals that were being sent to a warship from Jask, in the Persian Gulf. The distance traversed was 6,249 nautical miles, and the sending apparatus was of Marconi pattern; the receiver was the Marconi magnetic detector.

Locomotive Controlled by Wireless.—Tests are being made on the Canadian Pacific Railway at Toronto, Ont., with a locomotive operated and controlled by wireless. Mr. F. W. Prentice is the inventor of the system, and the tests are said to have proved to be satisfactory and effective. Mr. W. J. Camp is assistant manager of telegraphs of the Canadian Pacific Railway with headquarters at Montreal.

Wireless Between New York and London.—Mr. Godfrey C. Isaacs, managing director of the Marconi Wireless Telegraph Company, London, England, states that high-powered wireless stations to be erected in New York and London for the direct transmission of messages between these two cities will be open for the receipt and transmission of messages by January 1, 1913. In addition to the sending stations there will be central offices in London and New York where messages will be received and forwarded to the stations.

Wireless Experiments During Eclipse of Sun.—During the eclipse of the sun on April 23, experiments are to be made in Paris to note the effect of the related phenomena upon wireless waves. It is well-known that electromagnetic waves are propagated further in the absence of sunlight than when the sun shines, one theory to account for this action being that the ultra-violet rays of the sunlight have an absorptive effect. In making the proposed tests, messages will be sent shortly before, during, and after the eclipse, and the effect of the absence of the sun's full light upon the emitted waves will be noted.

Dr. De Forest Arrested.—Dr. Lee De Forest, the well-known inventor of a wireless telegraph system was arrested in Palo Alto, Cal., March 27 on an indictment found in the southern district of New York charging misuse of the mails. James Dunlop Smith, S. E. Darby, E. E. Burlingame and the Ellsworth Company are also indicted for the same offence and are co-defendants with De Forest. It is charged that the defendants attempted fraud by inducing certain persons to send to the Ellsworth Company and to the Fiscal Agency Company, of New York, money for stock in the Radio Telephone Company, a New York corporation; the Great Lakes Radio Telephone Company, the Atlantic Radio Company and the Pacific Radio Company, the three last Arizona corporations. The defendants are charged with having misrepresented conditions in telling the complainants that the corporations in question were paying dividends from the net profits of commercial operations.

Experimental Wireless Station.—Mr. John Hays Hammond, Jr., of New York, is erecting a wireless experimental station on the sea front at Gloucester, Mass., which, it is stated, will be one of the most complete of its kind in existence. It is being established for the especial purpose of developing means of securing selectivity in wireless telegraphy and telephony.

The aerial is to be supported by two towers 340 feet high set 350 feet apart. The power installation will comprise eight complete wireless telegraphic systems, and also a system for telegraphing and telephoning over a searchlight beam. There will be two specially constructed high-frequency alternators giving 100,000 alternations per second, and developing an output of two kilowatts. These machines will be used for experimental development in wireless telephony. There will also be two five-kilowatt motor generator sets, having a frequency of 1,000 cycles per second. These will be employed for experimental research in wireless telegraphy. There will be a one-half kilowatt 250-volt direct current generating set for use with arc telephony. Besides this apparatus, there will be equipment for an induction-coil set. The station will also be used for the control of wireless dirigible torpedoes.

Consolidation of United Wireless and Marconi Companies Completed.

The trustees in bankruptcy of the United Wireless Telegraph Company and the United States district court at Portland, Me., have accepted the plan to consolidate the former company with the Marconi Wireless Telegraph Company. Under this new arrangement the stockholders of the Marconi Company and the stockholders of the United Wireless Telegraph Company will combine their interests by the formation of a new corporation, with an authorized capital of $10,000,000, or by increasing the present capital of the Marconi Wireless Telegraph Company of America from $1,511,200 to $10,000,000. The physical assets and patents of the United Company, excluding the claims against former president Christopher C. Wilson, who is now in prison, and George H. Parker, of Seattle, will be turned over to the new or enlarged company at a valuation of $700,000.

The physical assets and patents of the American Marconi Company will be turned over to the new or enlarged corporation at a valuation of $1,511,200. The Sir Oliver Lodge American patents will be turned over by the Marconi Wireless Telegraph Company, Limited, of London, at a valuation of $788,800. The agreement is that no shares of stock in the new or enlarged company, beyond the shares of $3,000,000 par value, will be issued except for cash, and not for less than par.

The Railroad.

Mr. W. W. Ryder, general superintendent of telegraph, New York Central Lines, Chicago, Ill., was a New York visitor, April 11.

Mr. F. C. Batchelder, an old-time telegrapher, was elected president of the Baltimore & Ohio Chicago Terminal Railroad Company, Chicago, Ill., April 11.

An Operator Rewarded.—Mr. M. D. Wheaton, operator for the Pennsylvania Railroad at Wooster, Ohio, recently discovered a broken rail in time to prevent a possible wreck. For his alertness and promptness he was presented with a gold watch by the railroad company.

An Accident Avoided.

Much has been said concerning the many ways in which the telephone has helped the railroads after an accident has occurred, such as getting information to headquarters and the starting of wrecking and relief expeditions to the scene of the disaster. From the middle west comes a tale which demonstrates that the telephone played an important part in an accident "that did not happen." A track-walker on one of the trans-continental railroads in stepping back upon the right-of-way after a fast train had passed, noticed lying along the rails a broken flange that had ripped off one of the wheels of a car. The track-walker hastened to a siding switch, which was equipped with a Western Electric iron case telephone set, and told the dispatcher of his discovery. The dispatcher immediately telephoned ahead and had the train stopped, the damaged car removed from the train and thus a possible accident was prevented.

Pennsylvania Railroad's School of Telegraphy.

Since the establishment of the school of telegraphy in 1907 at Bedford, Pa., by the Pennsylvania Railroad Company, there have been enrolled 364 students, 214 of whom have been graduated and are now employed as telegraphers. In addition to the miniature railroad, engines and cars, a regular system of manual block signals, with cross-overs and sidings, has been installed at the school. Dispatching trains by telegraph and telephone is taught while the students are also given a full course in agents' work, such as filing of tariffs, keeping reports, filling out standard blanks and keeping the necessary records.

The school is in charge of Mr. J. C. Johnson, superintendent of telegraph of the Pennsylvania Railroad, Philadelphia, Pa., and Mr. Thomas Saddington is the resident manager of the school.

An account of this school was printed in our issue for February 16.

Increasing Use of the Telephone for Train Dispatching.

The New York Central and Hudson River Railroad Company recently placed an order with the Western Electric Company for forty-five telephone sets and miscellaneous supplies, to be used in extending its system; and later placed a further order for seventy similar telephone sets, fifty-four transmitter arms, thirty portable telephone sets with the same number of line poles, sixty test panels and a considerable quantity of miscellaneous supplies.

The Davenport & Muscatine Railway Company, operating between Davenport and Muscatine, Ia., a distance of about 25 miles, is installing a four-selector and telephone way-station equipment, four selector semaphores and four siding telephones. The Gulf, Florida & Alabama Railway of Pensacola, Fla., has adopted the telephone and given the Western Electric Company an order for equipment for 100 miles of line, consisting of twenty selectors, fifteen siding sets, twelve portable sets and the necessary line material.

The Lehigh Valley will install a special yard dispatching circuit consisting of eight complete selector stations, and has also ordered one hundred and forty portable telephone sets with line poles. A total of fifty-five wall telephone sets and miscellaneous material for train dispatching circuits is going to the Norfolk & Southern Railroad Company, while the Norfolk & Western has ordered ninety adjustaphones (transmitter arms) with the necessary generator sets and miscellaneous pole line hardware for two dispatching circuits.

The Chesapeake & Ohio recently installed forty-six additional desk type telephone sets with miscellaneous line material; and for use on the line between Columbus, Ga., and Birmingham, Ala., the Central of Georgia has ordered thirty portable sets and line poles. The Baltimore & Ohio will shortly install thirty-five additional way station outfits.

Convention of Railway Telegraph Superintendents.

The annual convention of the Association of Railway Telegraph Superintendents will, as previously announced, be held in New York, beginning June 4. The headquarters of the association will be at the Waldorf-Astoria, New York's celebrated hotel, and the meetings will probably be held in the main auditorium in the United Engineering Societies Building, No. 29 West Thirty-ninth street, which building is only a few blocks from the hotel, and where ample space will be provided for exhibits. It is interesting to note in this connection that the United Engineering Societies Building was erected largely through the generosity of Mr. Andrew Carnegie, and is the headquarters of most of the national engineering societies.

The programme for the meeting is a comprehensive one, and will include the reading and discussion of many valuable and interesting papers, which will occupy three days' time. There is much to see in New York and the entertainment committee, realizing that the visitors cannot see everything during their short stay, has used good judgment in mapping out a plan for

Digitized by Google

the entertainment. The business of the convention is, of course, of the first consideration, but the combination of business and pleasure has been skilfully arranged.

The first business session will be held on Tuesday, June 4.

In the afternoon the ladies will be taken on a sightseeing tour in cars furnished by the Railway Telegraph & Telephone Appliance Association, and in the evening the New York Telephone Company will give a theatre party.

On Wednesday morning the ladies will go on a shopping tour and in the afternoon the men will visit the main operating department of the Western Union Telegraph Company and the Cortlandt street exchange of the New York Telephone Company. At 5 p. m. a trip will be made to Coney Island on a special steamboat provided by the Appliance Association.

On Thursday the ladies will visit the art galleries, and other places of interest, and in the evening there will be a roof garden party given by the Appliance Association.

On Friday the entire party will board a special train on the Erie Railroad at 9:30 a. m. and make a trip to the Edison works at West Orange, N. J. The visitors will be entertained at luncheon at the Country Club at West Orange, after which they will return to Jersey City where they will board the Western Union cable steamer *Robert C. Clowry* or some other available boat. They will then be conveyed to Travers Island and entertained at a clambake given by Mr. Belvidere Brooks, in behalf of the Western Union Telegraph Company.

The Entertainment Committee has given much time and attention to the work of arranging for the welfare of the superintendents and their families, and everything that is possible is being done to make the visit an enjoyable one. The committee consists of Messrs. L. S. Wells, L. B. Foley, E. P. Griffith, J. C. Johnson, E. E. Hudson, W. F. Crowell and R. A. Patterson.

Mr. P. W. Drew, superintendent of telegraph, Minneapolis, St. Paul & Sault Ste. Marie Railway, Chicago, Ill., is the Secretary of the Association, and he will be glad to give further information to those desiring the same.

Overhead Crossings.

At the recent meeting of the American Railway Engineering Association in Chicago part of the report of the committee on electricity was devoted to the specifications for overhead crossings of electric light and transmission lines. The sub-committee has been working in conjunction with a joint committee representing the National Electric Light Association, American Institute of Electrical Engineers, American Electric Railway Association, Association of Railway Telegraph Superintendents and representatives of large telegraph and telephone companies. The report of the joint committee and the report of the committee on electricity of the American Railway Engineering Association agree in the main, although there are points of divergence in a number of particulars. The specifications for overhead crossings as reported by the committee of which Mr. G. W. Kittredge is chairman were taken up paragraph by paragraph. In every instance except one, where there was a difference between this report and that of the joint committee, the paragraph of the joint committee was adopted, in deference to the wishes of the other associations mentioned. In one case, however, the steam-railroad men stood immovable, and this was in relation to paragraph 18, in which Mr. Kittredge said that the committee felt that it could not adopt the language of the joint committee's report. This paragraph relates to conductors, and as adopted by the American Railway Engineering Association reads as follows:

"18. Strain insulators shall be used in guys from wooden poles carrying any power wire of less than 6600 volts, provided the guys are not through-grounded to permanently damp earth. Strain insulators shall not be used in guying steel structures nor required on wooden poles carrying wires all of which are 6600 volts or more, provided the guys are through-grounded to permanently damp earth."

Obituary.

Elmer E. Shawn, aged fifty-one years, an operator for the Associated Press in Denver, Colo., died in that place March 26.

Olga Ruth McKenna, aged 22 years, daughter of Mr. F. J. McKenna, of the Postal Telegraph-Cable Company, Pittsburgh, Pa., died on March 20.

Frank P. Moore, an old time telegrapher formerly of Omaha, died at Sioux City, Iowa, of pneumonia March 17. His remains were buried in Fremont, Neb.

C. E. Case, manager for the Western Union Telegraph Company at Norwich, Conn., died in that city March 25. He was in the company's employ over fifty years, and served as a volunteer in the Army during the civil war.

I. W. Copeland, aged 65 years, manager for the Western Union Telegraph Company at Troy, N. Y., for forty years, died suddenly at his home, April 10. Mr. Copeland served as a soldier throughout the civil war, and he was one of the best-known telegraphers in the east. He attended the recent dinner to Mr. Theo. N. Vail.

Jesse Lantz, age 68 years, an old-time telegrapher and a member of the United States Military Telegraph Corps during the Civil war, died at White Plains, N. Y., March 20th. This is the thirteenth death among the members of the United States Military Telegraph Corps reported since the Atlantic City, N. J., reunion last September. Mr. Lantz, at the breaking out of the civil war, was employed by the Pennsylvania Railroad at Harrisburg and after hostilities had ceased he entered the service of Jay Cooke & Co., bankers at Philadelphia, Pa.

Some People Certainly Have "Hard Luck"

and make no end of mistakes. Others use ***The Calculagraph.*** It subtracts the time-of-day a telephone toll circuit is put up, from the time-of-day the conversation ends and prints the number of minutes and fractions of a minute consumed in the use of the line. This is done without brain assistance and there is no possibility of clerical errors.

The Calculagraph

thus relieves the toll operator of a lot of labor and insures payment for all "excess time" in the use of circuits. The increase in revenue from this source is often enough to pay for the Calculagraph the first month it is used.

TELEPHONE
BOOK

Telephonology

BY
H. R. Van Deventer

642 pp. 800 illustrations.

$4.00 (17s).

¶ The Third Edition (1912) is now ready.

¶ It has much new data, fresh material and is again right up to the minute on modern equipment.

¶ Not only the automanual system, wireless telephony and railway systems but also multiplex telephony and telegraphy are covered in full detail.

¶ The entire work has been thoroughly revised and enlarged to 642 pages.

¶ It is a complete encyclopedia for the practical worker.

¶ It covers Erection, Exchanges, Troubles, Testing, Switchboard, Circuits, Batteries, Systems, Party Lines, Wireless, etc., etc.

The "Western Union Special."

A FEW TIPS TO OPERATORS AS TO EFFICIENCY ON THE UNDERWOOD TYPEWRITER.

Now that the Western Union Telegraph Company has made its typewriter equipment uniform by the purchase of 10,000 machines of the Underwood Company, the necessity for a clear understanding of that typewriter on the part of the Western Union operators is apparent.

A short time ago most of the "mills" used by the many Western Union offices were the property of operators. The equipment consisted of machines of every character—single keyboards, double keyboards and double shift key machines—a bewildering array that left the operators unfamiliar with the operation of any one of them.

In the telegraph business the experiences of the operator proved the necessity for concentration on one machine, and now through the record breaking order recently given to the Underwood Company, the typewriter condition has been entirely changed. The "knights of the key" this year are welcoming information that will make them also "knights of the writing machine."

The Underwoods which are being shipped by thousands to the various Western Union offices are machines specially constructed for the telegraphic service, selected after an eight months' test in competition with all other makes. They are especially adapted to the work of telegraphic transcription with a keyboard made up to fit the needs of the operator.

In telegraphic work, and particularly the "press" branch of it, speed is a necessity. It may be considered fortunate for operators, therefore, that the Underwood machine was chosen by the Western Union because that machine holds every medal ever awarded for speed work in typewriting. In the Western Union "Special" the machines are not intended to employ the small letters of the alphabet. It is known as an "all cap" keyboard equipped with special characters. The shift key is only necessary to obtain the characters on the upper row and right hand side of the bank of keys. It is therefore "non-shifting" except for these special characters and fractions. So far as telegraph work goes this keyboard is supposed to be the ideal one for practical work, as the Western Union main offices and offices thus far equipped with these new machines will bear evidence.

AFTER MACHINE IS RECEIVED.

It should be remembered by the Western Union man who receives an Underwood typewriter that the machine is shipped to his office in a manner peculiar to it, so that it is next to impossible for it, under ordinary conditions, to be broken in transit. It is, however, an easy matter, through want of knowledge, to injure the machine in unpacking it, for which reason the machines are sent to the large branch offices of the Underwood Company and from there sent to the Western Union offices with instructions to hold until a repair man can set the machines up. It would not be out of place to state that in shipping these machines they are *suspended* in their packing cases with special protecting spring devices patented by the Underwood Company and tested out under extreme conditions. This makes it necessary that no Underwood typewriter should ever be taken out of its box except by unscrewing all the screws around the outer edge of the *bottom* of the box through which four bolts are placed and lifting the suspended machine out in this manner.

CARE OF THE MACHINE.

Possibly the best advice to be given the operator, as an introduction to the Underwood typewriter, is the necessity for proper care of it. There is nothing more important than this if the Western Union serivce is to be made more efficient, which is one reason for this record-breaking purchase of typewriters, the second being the desire of the telegraph company to relieve the operators from an expense to which they had for years been subjected in purchasing their own machines and keeping them in condition. In the first place no typewriter should be allowed to remain in an office, except when in use, unless it is covered with a rubber cover. In addition to this it should be treated to at least one daily cleaning. All working parts of it should be gone over with an oiled rag, but the machine should be carefully cleaned off after this with a clean piece of cheese-cloth. Oil from the oil-can should be used only on the running parts, after which these parts should be wiped off with a clean rag. Under no circumstances should the machine be flooded with oil, as the dust in any office will be caught by it and finally clog the action of the machine.

The type should be cleaned daily with a stiff brush which should always be used from right to left of the machine. In case the machine has been used with a heavily inked ribbon, it would be well to see that all type, particularly the a, e, o, u and m's are cleaned out with a pin before they are brushed. In cleaning the machine itself always brush the dust or dirt *back* of the type bar connections.

RIBBONS.

Each machine as it reaches the Western Union office is equipped with a purple copy *Underwood* ribbon made with special care for the machine and fitted with an exactness which does not apply to other ribbons made by other firms for the Underwood. Trouble, which the operator has in many cases with the ribbon, will be obviated entirely by the use of this ribbon rather than the ribbons of other makes in the open market. Careful instructions for changing the ribbons go with each machine, so that it is not necessary here to write anything in regard to this matter.

ESTABLISHING MARGINS.

The devices which enable the operator to establish margins with the Underwood are simple. They are located underneath the scale, one at either side and each has a pointer which, when pushed either to the right or left, indicates the limit of the writing line in either case. In order to establish a margin, all that it is necessary to do is to pinch either of these little devices and

Digitized by Google

to push them along the rod on which they run.

In order to give the proper information as to margins, it is well to use as an example the regulation telegraph blanks used by the Western Union Telegraph Company. These blanks are uniform, eight inches in width but of different sizes as to length. The regulation blank for a "ten-word" message—the shortest blank used, has a writing surface about three and one-quarter inches deep. The Day Letter blank is about four and three-quarter inches as to writing surface, while the writing surface of the Night Letter is about four and one-half inches.

CENTERING THE BLANKS.

To accomplish the best results with the blanks, the right hand margin stop should be set at what would be the second space on the scale and the left hand margin stop at what would be the seventy-second space on the scale. Then the paper fingers, which are the little clips, one on each side on top of the platen, should be manipulated as follows: The right hand paper finger should be pushed to the left so that about one and one-eighth inches of the platen is exposed between the right frame of the machine and the small rubber roller on the paper finger. The left hand paper finger should be pushed over to the extreme end of the platem.

As all of these Western Union blanks are inserted in the machine exactly in the center between these paper fingers, the outer edges of each blank will divide the paper fingers in the open space under the little rubber rollers exactly in the center. This will leave a margin on each side of the blank of one-half inch, which will make the telegram take on a correct typewriter appearance.

THE CABLE MESSAGE FORM.

There is very little difference between the size of the Night Letter form and the Cable Message form except that in the latter there is less writing surface. It is possible, by a little crowding, to get very nearly five inches of writing surface on the Night Letter form but only three and three-quarter inches on the form devoted to cable messages.

THE TYPE-BAR GUIDE.

The Underwood is so constructed as to make the operation of it extremely simple. It is equipped with the only type-bar guide that secures absolute, perfect alignment. The operation of the machine is easy because there is one rule that the machine always follows, viz.; that the typewriter, when a key is depressed, will print exactly in the center of this type-bar guide, which guide is located in the exact center of the machine and is the part behind which the ribbon is located. As the carriage is moved from right to left, the machine will print exactly in the center of the notch on the type-bar guide. By trying this out the operator will see how easy it is to throw the carriage to the right or left and insert a letter which has been omitted by mistake. This type-bar guide also forms a regulation guide for all printing. Wherever the center of the guide stands, there the machine will print.

POINTS ON TABULATING.

Each Western Union "Special" is equipped, like all Underwood machines, with a tabulator key located at the right hand upper corner. This key enables the operator to cause the carriage to move automatically from right to left and stop it at will, thereby obviating the use of the space bar. The tabulator stops are located on the back of the machine, each stop having a pointer arranged over a back scale which conjoins with the scale on the front. To cause the machine to move automatically, the tabulator stops in the back should be thrown out and moved on the running bar to any point desired. Four tabulator stops are furnished with each machine and these allow the carriage to make four tabulator stops from right to left.

In the use of the Western Union blanks, when it is necessary to make a paragraph, it will be found advantageous to move the first tabulator stop one-half an inch to the right of the first indicated tabulator stop which is 10. It will then be found that the carriage will automatically find its proper paragraph point at 5 on the front scale whenever the tabulator key is touched. This makes it unnecessary for the operator to space the space-bar, or operate the carriage release in order to find the paragraph point.

AS TO THE TOUCH METHOD.

This same tabulator can be used for the signature at the bottom of the telegram by placing the second tabulator stop from the right at 40 on the back scale. This would enable the operator, when the telegram was completed, to come to the proper place for the signature by making two depressions of the tabulator key; one that would bring the carriage to the first tabulator stop at 5, and another depression of the key to allow the carriage to move to the second tabulator stop at 40—the proper signature position. This would, as in the paragraph stop, obviate any use of the carriage release key, or the space-bar, and it is a valuable suggestion for the rapid transcription of telegrams.

Naturally, the telegraph operator, of the old school at least, has never been instructed in the modern touch method now generally taught in the schools; therefore he could not be expected to make the same speed on a machine as those who are now graduating from the telegraphic departments of the various commercial colleges. The points given here may, however, assist him to some extent in acquiring enough speed to do his work more satisfactorily.

THE UNDERWOOD KEYBOARD.

The keyboard of the Underwood is so arranged that the operator holding his hands in a natural position before it will rarely be called upon to use his right hand on the left hand side of the keyboard, or vice versa. If he is ambitious to learn the touch system of operating an Underwood, he will find a book on this method of operation among the various things that make up the equipment accompanying each typewriter.

Digitized by Google

The time has come when telegraphy is closely allied with the typewriter and when a part of the instruction in telegraphy must be devoted to learning the operation of the writing machine.

Telegraphers oftentimes accomplish great bursts of speed in operating the typewriter, even though they may not have received instruction in the commercial schools. Certainly the typewriter has made a great change in the method of "receiving," making the "stuff" as it comes over the wire, instead of the old Morse hit or miss abbreviations, a legible result which goes red hot from the machine to the thankful printer. The typewriter has changed not only the method of telegraphic "receiving," but the ordinary methods which, up to within a few years ago, prevailed in newspaper offices. Woe betide the telegrapher or newspaper man today who doesn't own, or at least operate, a typewriting machine.

A FINAL SUGGESTION.

One suggestion that can be used by all operators to advantage and one which very few typewriter operators understand, is the instantaneous leading in to the machine of a telegraph blank or any other paper with the same motion used to draw out the written sheet of paper.

With this method it is possible, particularly in the "short word" message, to draw a new blank into the machine to the proper printing point for the date or any other line as soon as the blank already typewritten is drawn out. To accomplish this the new blank should be inserted into the machine between the platen and the paper upon which the operator is writing *before* the old blank is taken out. As soon as the signature is made on the first blank, the rapid drawing out of it will insert the other to the correct position for writing. With some practice the operator will be able to throw the new blank to any point on the paper where he desires to begin without any use whatever of the platen knobs.

The suggestions as offered above are only a few for the primary assistance of the new telegraph-typewriter operator. Experience is the best teacher. No one is more clever at inaugurating helpful methods than the operator himself. Therefore to obtain further instructions for the technical operation of the typewriter, the operator is referred to the literature which accompanies each machine.

Municipal Elections.

The Gamewell Fire Alarm Telegraph Company has secured the contract to supply the city of St. Louis with a large number of additional fire alarm telegraph boxes.

New York Fire Alarm System.—Mr. Joseph Johnson, fire commissioner of New York, recommends that a new fire alarm system be installed and that isolated sites for fire alarm telegraph stations be provided.

Municipal Electricians.—The executive committee of the International Association of Municipal Electricians met at Peoria, Ill., April 15, to arrange a date for the annual convention of that association, which is to be held in Peoria during the summer. The committee also arranged for papers to be read at the meeting. Mr. C. R. George, city electrician, Houston, Tex., is the secretary of the association.

Proceedings of Municipal Electricians' Convention.—The proceedings of the sixteenth annual convention of the International Association of Municipal Electricians, held at Atlantic City, N. J., September 12-15, 1911, have been published in book form, and copies have been sent to the members. The volume contains nearly 200 pages and is neat in appearance and mechanical execution. The frontispiece consists of a portrait of Mr. John W. Kelly, Jr., of Camden, N. J., president of the association, and portraits of other officials are scattered throughout the pages.

Concrete Telephone Poles.

The American Telephone & Telegraph Company has erected a number of experimental concrete telephone poles between Bloomington and Wilmington, Ill. These poles are thirty feet long, six inches square at the top and twelve inches square at the ground level, weighing about 2,000 pounds each. They are made in the form of a hollow square with walls two inches thick which are reinforced with steel rods. Cross arms are bolted on through holes left in the concrete when the pole is cast, and steps are made of through bolts provided with a shoulder, holes for these also being left during the molding of the pole.

Western Union Philadelphia News.

The first dinner of the Dot-and-Dash Club will be held on the evening of May 11. It will be called a "Reminiscent" dinner, and no doubt some of the old-timers will have something to say that will be very interesting. The club is growing and meeting with much success.

Clayton, Del., is connected by a loop from the main line. A few days ago the loop failed to work and a lineman found tangled up in the wires a beautiful silver crane which had broken its neck in its efforts to free itself from the wires. The bird was shipped to Mr. R. C. Murray, plant chief, this city, and was placed on exhibition in the main office.

Telegraph and Telephone in East Africa.—The Governor of the East Africa Protectorate reports that on March 31 of last year there were 2,261 miles of telegraph wire and 1,016 miles of pole line in the protectorate. There were 304 miles of telephone lines carried on 60 miles of pole line and 300 telephones were in use at that time.

The Secret of Success.—Col. Theodore Roosevelt was recently asked, "What is the secret of success?" His reply was: "There is no secret about it. It's the simplest thing in the world. Just do what you have to do and do it right away and as well as you possibly can. What good is a motto? Just rush out and attack the breastworks."

Digitized by Google

Western Electric Company's Report.—In making comparison between the business done by the Western Electric Company during the fiscal years of 1910 and 1911, as shown by its annual report, account has to be taken of the fact that the fiscal year 1910 had thirteen months. Making twelve-thirteenths of this year's business for purposes of comparison, the report for 1911 shows gross sales of $66,211,975 against $63,115,512 for 1910. The increase in manufacturing costs and expenses more than offset this increase in gross receipts, however, leaving net earnings of $4,135,201 for 1911 compared wth $5,002,308 for 1910. The 1911 balance available for dividends of nearly 22% is more than twice the regular 8% dividend rate plus the usual yearly extra 2%. The surplus on hand after deducting interest charges, dividends and amount paid to reserve. is $980,292 for 1911 as against $1,554,732 for 1910.

Western Electric News.—The Western Electric Company has begun the publication of a monthly journal called *The Western Electric News*. The headquarters are in New York and the Board of Editors consists of P. L. Thomson (Editor-in-Chief), E. A. Hawkins, C. H. Johnson, R. Raymond, W. F. Hendry, F. H. Leggett and G. C. Pratt. The first number has an attractive front cover in colors.

Telegraph Service of a Large Newspaper.—During the week ending March 30, 530,000 words were received by telegraph by the *New York Times*. Of these about 350,000 words were Associated Press matter. The exact total of "special dispatches," as shown by the bills of the telegraph companies, was 181,484 words, including 25,859 words foreign news. The foreign service included 24,910 words transmitted by wireless telegraphy.

The Vibroplex.

The new model direct point Martin vibroplex is an entirely new departure in sending machines and it is claimed has solved the sending machine problem. Dots and dashes are made on the same contact point, thereby insuring perfect signals.

This up-to-the-minute transmitter has an advantage of at least 50 per cent. over the old style Martin vibroplex which has been so popular for the past ten years. One of the chief reasons why these transmitters have proven so satisfactory is that Mr. Martin is an expert telegrapher and has at heart the welfare of the fraternity. It has been his constant endeavor and desire to give to the telegrapher that which is best. When he originated this art of transmission the discovery was received with scant approval. He was forced to give away hundreds of instruments in order to introduce them. He had to teach the operators how to manipulate them. Then, when their merit became known, competition sprung up. Some of these competitors were not telegraphers; they were utterly lacking in experience and their makeshift apparatus naturally had a temporary damaging effect on the good machines, but "the survival of the fittest" doctrine applies as well to transmitting machines as to anything else, and the Martin transmitter has emerged from the battle unscathed, and victorious. Mr. J. E. Albright, 253 Broadway, New York, is the sole selling agent for this machine.

The Calculagraph.

The necessity for a device to record elapsed time from the beginning to the end of an event or operation led to the development of the Calculagraph. By the use of this instrument there is no possibility of clerical errors and there is no chance for falsifying the record by tampering with the machine.

Several different models of the Calculagraph are made, arranged for recording time in different denominations. One model records elapsed time in minutes and fractions of a minute, and is used in

THE CALCULAGRAPH.

every telephone exchange in the United States and Canada where a considerable amount of toll business is handled. This type of Calculagraph, it is stated, is also the standard apparatus for timing toll messages in every country in the world where telephones are used, and the manufacturers are now executing an order from the French government for one hundred of these machines for use in its telephone exchanges.

One type of Calculagraph records elapsed time in hours and minutes, and another model in hours and tenths of an hour. These are very extensively used in manufacturing plants and in other industries where large numbers of persons are employed.

Western Union Affairs in Richmond, Va.

H. H. Cramer, who succeeded the late E. N. Dennis as night chief operator, has been promoted to be day chief operator, succeeding F. R. Veale, transferred to the cable service with headquarters at Atlanta, Ga. Mr. Thos. Farley, repeater man in this office for several years, has been promoted to succeed Mr. Cramer and S. V. Moody of the operating department has been appointed to succeed Mr. Farley. The

Digitized by Google

offices of superintendent, J. S. Calvert; commercial superintendent, F. O. Nourse, and district plant superintendent, J. B. Faulkner have been moved into the company's new headquarters in the Travelers Insurance building, recently constructed. The operating plant and commercial departments will be removed later.

Western Union New Main Office at Houston, Texas.

The Western Union Telegraph Company is completing a new main office at Houston, Tex., which will rank among the finest telegraph stations in the country. The operating department, which will occupy the second floor, will be equipped with apparatus of the latest design, and will have seventy-eight operators' positions, and a large repeater-outfit. Five sections of the new type switchboard will be installed and the dynamo plant will be of modern design.

Ample and commodious quarters are provided for the employes and every effort has been made to insure their comfort. The business or commercial office on the ground floor will be simply, but handsomely furnished and no effort has been spared to make it convenient and comfortable both for the public and the employes.

LETTERS FROM OUR AGENTS.

PHILADELPHIA POSTAL.

The annual ball of the Electrical Aid Society of Philadelphia, set for April 17, promises to surpass all former affairs both financially and socially.

Mrs. Taney has resigned, to go to Boston.

Mr. R. Gould, of New York, was a recent visitor on company business.

NEW YORK WESTERN UNION.

Sympathy is tendered to Mr. Joseph Piccolo, chief of the newspaper division, on the death of his father on March 31.

Mr. James L. Young, manager of the Gold Street office has been elected captain of Company "I", forty-seventh Regiment, N. G. N. Y. Captain Young is the youngest officer in the Guard and one of its best shots.

Mr. M. Walton Jones, formerly of superintendent E. M. Mulford's office, and for the past two years in the employ of the Guayaquil and Quito Railway, South America, has been promoted to the position of train master for that company.

J. Walton Smith, aged fifty-four years, a well-known New York telegrapher, for many years identified with this department and with the *World* Telegraph Bureau, New York, died at Atlanta, Ga., April 3. Mr. Smith recently went South for the benefit of his health.

Jas. T. Shain, aged 70 years, familiarly known as "Dock" Shain, died in New York on April 3. Mr. Shain was an old-time telegrapher and was well known in Philadelphia and other sections of the country. He had worked in this office for the past thirty-five years.

Courtland M. Cunningham, aged 59 years, a well-known New York telegrapher, died in Brooklyn on April 4. Previous to his coming to New York in 1878 he was employed at Omaha, Neb.

A new time stamp has been introduced in this department to record the arrival and departure of each employe. It seems to give satisfaction. Each member of the staff carries a card which he inserts in the clock on arriving and departing from the office.

A certificate of membership in the Telegrapher's Mutual Benefit Association, 195 Broadway, New York, affording protection for the family and dependents in the amounts of $500 or $1,000, which is at once available and cannot be diverted from its mission, should be held by every eligible person between the ages of 18 and 45 engaged in telegraph and telephone service, either commercial or railroad. If those not now members could realize and fully understand the stern necessity for beneficial help too often experienced by bereft families, would they not make earnest effort to secure such provision? Write for particulars.

You Don't Eat Half

an apple and throw the rest away, do you?

Why only glance through this and other issues of TELEGRAPH AND TELEPHONE AGE when you can receive the full benefit by reading the copy through.

Because some see TELEGRAPH AND TELEPHONE AGE at the office only, they don't get a chance to read it through carefully.

Why not subscribe for a copy to be sent home, and read TELEGRAPH AND TELEPHONE AGE when you are at ease—when you can absorb its practical help best?

Mail $2.00 for the year to E. Schwartz, General Subscription Agent, 53 Avenue D, New York,

FOR SALE.—Yetman Transmitter without typewriter attachment. Perfectly new. The best transmitting device on the market. Address, Yetman, care of TELEGRAPH AND TELEPHONE AGE, New York.

Manufacturer of Electrical Instruments and Light Machinery. Experimental Work a Specialty
108 PARK ROW, NEW YORK Telephone 910 Worth

TRANSMITTING MACHINES
I am placing on the market improved YETMAN TRANSMITTING TYPEWRITERS, and KEYBOARD TRANSMITTERS without typewriting features. Am prepared to exchange, repair or rebuild all old machines. Write for catalogues and particulars to
James Uncles, NORTH ADAMS Massachusetts

Rubber Telegraph Key Knobs.

No operator who has had to use a hard key knob continuously should fail to possess one of these flexible rubber key caps, which fits snugly over the hard rubber key knob, forming an air cushion. They render the touch smooth and the manipulation of the key much easier. Price, fifteen cents. J. B. Taltavall, TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

Ideas As a Business Asset.

There is probably nothing in this world any more valuable than ideas, notwithstanding the fact that there is no living person who has not had a goodly share of them during his life time. No one is too poor to have some, yet comparatively few derive much, if any, benefit from them because they either belittle the importance of the lines of thought in which their mind turns or they are incapable of carrying into execution the suggestions of that little small voice which is endeavoring to urge each of us onward to success.

Did it ever occur to the reader that ideas, or rather the faculty of evolving, accumulating, and promoting them, might be made a profession or line of business? If not, it should be known at once that no one has ever achieved any great degree of success in this world without pursuing this line of thought and action.

The head of one of our greatest industries as a boy worked several years in a small country store for five dollars per week. Business was so dull that in order to kill time he used to dress the shop window with different kinds of goods to represent animals or machinery, and thereby unwittingly attracted the attention of the editor of the local newspaper who, when news was scarce, often referred to these unique displays. This free advertisement was read by a merchant in an adjacent town who wrote to the boy and offered him $10 per week. The boy accepted. The new employer then told the boy that he was not hired simply to sell goods over the counter to regular customers—anyone could do that, and he could get all the boys he wanted for $5—but that he was employed for the sole purpose of evolving ideas that would bring strangers into the store.

This was a strange proposition to him but he immediately put on his thinking cap and let his mind work overtime. The result was a large business soon came to his employer's store, and the store gained a state-wide reputation.

Naturally the "promoter's" services were in wide demand and each offer he received was succeeded by a better one until finally he found himself general manager of one of the biggest concerns in this country, and all the capital he had to start on was what we all have—ideas.

Probably the reader will say, "but I'm not a merchant, I'm a telegraph or telephone operator and not in a position to attract the public's attention." If so, that is where you make a mistake. What you need to do is to attract your employer's attention. Every now and then you have seen an improvement made in some apparatus that you have been using daily, and possibly may have thought of the same thing yourself, but you let it pass and a wiser man reaped the reward. Not only that, but when he suggests another improvement of some kind it will be found that the prestige he gained by his first effort will assure its consideration at least, and at the same time he advances a little nearer the center of the stage.

The point of this illustration is, get started. Do something, even if you fail. Do not stop if your first move is a failure; very few succeed at first.

Now, there are many things that might be improved in the telegraph service, both mechanically and electrically. If you are of a mechanical turn of mind devote your attention to bettering or cheapening the construction of the apparatus before you; if electrically inclined, to improving their operation by means of some new method. There are many things needed. For example: A really satisfactory means of eliminating inductive effects due to the proximity of wires; a self-adjusting or compensating single line Morse relay; a means of duplexing a wire without using an artificial line for the purpose of balancing it; a simplified "double loop repeater" that will immediately disclose on open circuit on the receiving side of the extra loop.

A fortune awaits the one who solves any one of the first three problems mentioned; they are not impossible of solution. The day has arrived when we can safely say, "there is nothing impossible, it is merely a matter of time and the right man." Try to be that man!

Personal.

Miss Myrtle Stumm, daughter of Mr. F. A. Stumm, a well-known old-time telegrapher, but now retired, was married April 9, to Mr. F. D. Graham, at Arcola, N. J.

Mr. W. Noble, who has been appointed assistant engineer-in-chief of the British postoffice, London, England, was employed as an operator in the English telegraph service at Aberdeen, Scotland, until the age of 33 years. He has been in the engineering branch of the service at London for the past eighteen years.

French Wireless Operators Shot by Arrangement.—Four French wireless operators at Fez, Morocco, were killed recently, it was thought, by the Moors, who are in rebellion against the French. Later dispatches, however, state that rather than fall into the hands of the Moors, by whom they were to be inevitably captured, they, by lot selected one of their number to shoot the other three and then kill himself, which arrangement, it is stated, was carried out.

In Memory of Wireless Operator Phillips of the "Titanic."—The telegraphers of Madrid, Spain, have decided to place the portrait of J. A. Phillips, the wireless operator, who lost his life in the "Titanic" disaster, in a place of honor in the principal operating room. They wll also ask the International Bureau at Berne, Switzerland, to take some steps toward perpetuating the memory of the brave operator.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. E. J. Nally, vice-president and general manager, New York, has gone on a trip through the South and West and will be absent until about the middle of May.

Mr. G. H. Usher, general superintendent, and Mr. G. W. Ribble, district superintendent, Atlanta, Ga., visited Jacksonville, Fla., recently, on an inspection tour.

Mr. F. F. Norton, superintendent of traffic, New York, is on a trip through the west on company business.

Mr. Guy E. Paine, Chicago, Ill., superintendent of the second district, has resigned to engage in other business. He has associated himself, as a partner, with well-established insurance brokers in the South.

Mr. D. H. Gage, Jr., of the electrical engineer's office, has gone to Chicago on company business. Mr. A. J. Eaves of the same department has returned from Washington where he went on business connected with the engineering service.

A conference of managers of the second district of the Eastern Division was held in New York, April 25 and 26. Those present were Mr. E. Kimmey, superintendent, New York, and the following managers: F. Orchard, New London, Conn.; F. H. Dernell, Burlington, Vt.; T. F. Burke, Poughkeepsie, N. Y.; S. H. Flint, Bridgeport, Conn.; M. L. Barns, Troy, N. Y.; C. F. Horstman, Schenectady, N. Y.; B. F. Ziegler, Wilkes-Barre, Pa.; J. C. McGeehan, Hazelton, Pa.; A. C. Ackerman, Jersey City, N. J.; J. G. Sutliff, Elizabeth, N. J.; H. A. Guyon, Yonkers, N. Y.; C. W. Oram, New Brunswick, N. J.; W. B. Hynds, Norwich, Conn.; J. C. Churchill, Meriden, Conn. They all attended the Mapnetic Club dinner April 24.

Much sympathy is being expressed for Mr. George M. Eitemiller, of the Detroit office of this company, in the loss of his son, Floyd, in the "Titanic" disaster, April 14. Mr. Charles C. Adams, second vice-president, New York, personally tendered Mr. Eitemiller his heartfelt condolences and all the other officials at headquarters expressed themselves feelingly in regard to Mr. Eitemiller's bereavement. Everyone in the service, from the highest officials down, condole with that gentleman and feel that his great bereavement to a large extent is theirs.

The Mackay Telegraph & Cable Company will shortly lay an additional cable across the bay at Galveston, Tex. It will be a 20-conductor armored submarine cable, 12,000 feet in length.

Atlanta Banquet Postponed.—The third annual banquet of the Postal Telegraph Club of Atlanta, Ga., which was to have been held April 20 has been postponed until after the Grand Opera week, which covered the same date. Mr. L. A. Minor is secretary of the club.

Digitized by Google

Newport Messengers Ride to Boston on Bicycles.—Lester Martin and Peter Reid, two Newport, R. I., messengers of the Postal Telegraph-Cable Company, recently rode to Boston and back on their bicycles. They spent a day in Boston sightseeing as guests of the Boston messengers.

Telegraph Lines Submerged in Mississippi River Flood. — During the recent disastrous floods in the South, much damage was done to telegraph lines. Photographs received by Mr. W. I. Capen, general superintendent of plant, Postal Telegraph-Cable Company, New York, show how the company's lines suffered in the vicinity of Memphis, Tenn. Poles twenty-five high were entirely covered by water. One of the photographs shows linemen in a boat at work on the line with the water up to the cross-arms.

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr. E. J. Hall, chairman of the executive committee, has returned from a trip to South America. He visited cities on the eastern and western coasts and the Panama canal.

Mr. C. H. Murphy, general superintendent of time service, New York, has returned from a business trip to the Mountain and Pacific Divisions, having visited all of the large cities on the coast.

April 19 was the 51st anniversary of the capture of Mr. W. J. Dealy, general superintendent of the commercial news department of the Western Union Telegraph Company, New York, at the breaking out of the Civil War. Mr. Dealy was no doubt the first prisoner taken by the Confederates.

Mr. D. C. Dawson, district traffic superintendent, St. John, N. B., who has been spending several months on the Pacific Coast stopped off at New York recently on his return to St. John and called on friends.

Mr. P. D. Callum, division solicitor, New York, has been appointed commercial agent and attached to the staff of Mr. E. M. Mulford, division commercial superintendent, New York. Mr. Callum succeeds Mr. A. C. Kaufman who has been appointed division cable manager.

Mr. Frank V. Moffit, district commercial manager, Chicago, Ill., has been appointed manager at Toledo, Ohio, to succeed F. J. Krumling, deceased. Mr. Moffitt has been succeeded by Mr. L. J. Mink, formerly general solicitor, Chicago.

Mr. Jos. E. Fenn, division equipment inspector, Atlanta, Ga., in addition to his other duties, has been placed in charge, by supervisor of equipment L. B. Thompson, of the division storage battery systems, motor-generators, generators, etc. Mr. Fenn is one of the old-timers, an electrical engineer of ability and has had a wide general experience.

Mr. H. M. Armistead, manager of the Salisbury, N. C., office, has been transferred to Raleigh, N. C., as manager. Mr. Chas. M. Martin, of the Winston-Salem, N. C., office, has been appointed manager of the Salisbury office, to succeed Mr. Armistead.

Mr. F. D. Byrne, of the cable service at Duxbury, Mass., has been transferred to the cable department at Philadelphia, Pa.

Col. George L. Lang, former superintendent of telegraph of the Queen & Crescent Railway system, Chattanooga, Tenn., has been appointed special agent for the Western Union Telegraph Company, with headquarters in Chattanooga. Since leaving the Queen & Crescent system, Col. Lang has been engaged in other lines of business, and it will be gratifying to his many friends to know that he has returned to the telegraph service. He has had a wide and long experience in railway and commercial telegraphy and is well equipped to fill his new duties.

A meeting of Maine and New Hampshire managers was held at Portland, Me., April 26, and presided over by Mr. C. F. Ames, district commercial superintendent, Boston, Mass.

The following changes are announced by district superintendent J. R. Terhune, Nashville, Tenn.: Mr. Ozro Stanley of Memphis, Tenn., has been appointed local commercial agent. Mr. L. C. Smith has been appointed manager at Johnson City, Tenn., vice Mr. F. E. Frazier transferred to Ashland, Ky., as manager. Mr. C. W. Chenault, former manager at Ashland, has been appointed district manager, with headquarters at Nashville.

Mr. J. W. Collins, general traffic chief, Washington, D. C., has been promoted to be assistant to district plant superintendent R. J. Meigs at Philadelphia, Pa. Mr. Harry McKeldin has been appointed to succeed Mr. Collins at Washington, D. C.

Western Union and Marconi Traffic Arrangement.

The Western Union Telegraph Company has entered into a traffic arrangement with the Marconi Wireless Telegraph Company whereby the Western Union offices receive and deliver Marconigrams to and from Europe. The agreement provides for the extension of the Marconi system from the Pacific coast of the United States to Hawaii, China, Japan and the Philippines, thus giving the Western Union Company a wireless trans-Pacific service.

The English and American Marconi companies have agreed to construct a number of long distance wireless stations including the ones at London and New York, as previously announced in these columns.

At a special meeting of the Marconi Wireless Telegraph Company of America held in New York, April 18, the capital stock of the company was increased from $1,662,500 to $10,000,000.

Expropriation Proceedings in Louisiana. — The Western Union Telegraph Company has filed an expropriation proceeding at New Orleans, La., against the Louisville & Nashville Railroad Company for the right to maintain its telegraph poles and wires on the railroad company's bridge over Lake Ponchartrain at the Little Rigolets and Rigolets.

Digitized by Google

Heavy Telegraph Business on Account of the "Titanic" Disaster.

The greatest amount of telegraph business ever sent by the Western Union Telegraph Company from New York was handled April 18, in consequence of the "Titanic" disaster. Both the Western Union and the Postal Telegraph-Cable Companies had extra forces on duty for the occasion. The amount of press matter handled far exceeded the highest previous record.

The transatlantic cable service was also very heavy.

O. L. Turner, Superintendent, Dallas, Tex.

Mr. Owen L. Turner, district superintendent, Western Union Telegraph Company, with headquarters at Dallas, Tex., was born at Wabash, Ind., February 17, 1866, and entered the telegraph service in Auburn, Ind., July 4, 1882, as messenger.

With the exception of a year or two, in 1883 and 1884, during which time he was employed as operator on joint railroad work, Mr. Turner has been in the continuous service of the Western Union Company. Among the many positions held by him up to the present time, are, night chief operator at Ogden, Utah; assistant chief operator at St. Louis, Mo.; chief clerk to the superintendent at St. Louis, Mo., and, latterly, chief clerk to general superintendent L. McKisick, Dallas, Tex.

O. L. TURNER,
Superintendent, Dallas, Tex.

Western Union Pensions.—The brief and exact wording of the official announcement of the pension plan of the Western Union Telegraph Company was fully elaborated in our issue for April 16. The interpretation of the order as there given was authorized by the company, and explains how a pension in a given case can be determined. Every one interested should have a copy of this paper containing the article. Copies can be obtained at the office of TELEGRAPH AND TELEPHONE AGE, at 10 cents each.

The Cable.

The Commercial Cable Company's repair steamer "Mackay-Bennett" was chartered by the White Star Line and sent from Halifax April 17 to the scene of the "Titanic" disaster to search for bodies. A large number were found.

The cable steamer "Minia" of the Anglo-American Telegraph Company was placed at the disposal of the White Star Line and is now at the scene of the "Titanic" disaster searching for bodies from the ill-fated steamer.

British Pacific Cable. — The total number of words sent over the British-Pacific cable system, exclusive of inter-colonial traffic between Australia, New Zealand, and the Fijis, amounted to about 208,000 words in January, and about 211,000 in February, this year.

Japanese-Korean Cable.—The Communication Department in Tokyo, Japan, has decided to lay a new submarine cable between Shimonoseki and Fusan and also to erect a through wire between Nagasaki and Tokyo. There are already two submarine cables between Fusan and Shimonoseki. Besides these, Chosen and Japan are connected by a line between Wonsan and Matsuye, in Izumo Province, and another between Seoul and Osaka.

Central and South America Cable Rates Reduced.—The Central and South American Telegraph Company announces that on and after May 1 the rate "via Colon" and "via Galveston" to and from Colombia, Ecuador, Bolivia, Peru, Chile, Argentine, Uruguay and Paraguay will be reduced 20 cents per word. The reduction to and from those countries also applies to Europe, but not to China, Hong Kong, Chosen (Corea), Formosa, Japan, Philippines, Pacific Islands and Australasia.

A New Morse Telegraph System.

In our issue for April 16 we printed a description by Mr. J. W. Larish of a new system of Morse telegraphy invented by Mr. Patrick B. Delany, secrecy being one of the characteristic features of the system.

The illustration (Fig. 2) showing the form of the Morse characters as they are transmitted over the wire, was slightly defective due to imperfect etching of the plate by the engraver and gives a wrong record of what actually takes place. The dash and dot of the "n" in the word "shipping" and the two dashes and dot of the "g" should have been shown on the second line (the transformed characters) as well as on the first line. In the transformation Mr. Larish states that single dots always appear as such when in combination with dashes, exactly as in straight Morse. Therefore by adding a dot at the end of the last dash and one at the end of the third dash from the end of the lower line of characters a correct understanding will be obtained as to how the word "shipping" actually sounds to an interloper on the wire.

Obituary.

F. C. Simpson, aged 42 years, purchasing agent for the Missouri & Kansas Telephone Company, died in Kansas City, Mo., April 6.

Edwin Middleton, aged 84 years, who built the second telegraph line in the United States, died at Point Pleasant, N. J., April 19.

Thomas Jefferson Coolidge, Jr., of Boston, Mass., member of the board of directors of the American Telephone & Telegraph Company, died at his home in Manchester, Mass., April 14.

Maurice Brick, aged 60 years, a well-known old-time telegrapher, died in Washington, D. C., April 23. Mr. Brick was born in Watkins, N. Y., and was division chief at 195 Broadway, New York, for many years previous to 1883. He has been a resident of Washington, D. C., for the past twenty years.

George F. Eitemiller, son of Mr. George M. Eitemiller, the well-known old-time telegrapher, now with the Postal Telegraph-Cable Company, at Detroit, Mich., was a passenger on the ill-fated "Titanic," and was lost with the other passengers when the steamer sank. He was returning from a three-months' trip in Europe, as the representative of a Cincinnati automobile company.

Milan W. Russell, aged 55 years, a well-known telegrapher, died at Calgary, Alt., Canada, April 2. He was a native of Michigan and had occupied many positions in the railroad and commercial telegraph service throughout the West. In 1891, he became editor of Telegraph Age. Mr. Russell was prominent in Telegraphers' Brotherhood affairs, and a few years ago was on the editorial staff of the "War Cry," the official journal of the Salvation Army.

Albert L. Suesman, aged 68 years, a well-known old-time telegrapher, died in Oak Bluffs, Mass., April 13. He served in the Civil War as a member of the Twelfth Rhode Island Regiment. When he was mustered out of the military service he learned telegraphy and for several years was an operator in the Western Union Office at Providence, R. I., resigning as such to become manager at that point of the American Rapid Telegraph Company and later, of its successor organization, the Bankers and Merchants Telegraph Company. In 1885 he entered the service of the United Press as general Western manager with headquarters at Chicago. "Naturally alert, enterprising and possessed of the keenest intelligence." says Mr. Walter P. Phillips, his former associate, "he accomplished miracles in extending our service, pushing it westward until he placed it up and down the Pacific Coast, from Vancouver to Los Angeles and obtained for us firm alliances with newspapers of the greatest importance, such as the *San Francisco Examiner* and *Portland Oregonian*." After the absorption of the United Press by the Associated Press, in 1897, Mr. Suesman was with the Columbia Phonograph Company, in New York and Chicago, and later with the Bell Telephone Company in Kansas.

Mutilators of Telegraphy and Telephony.

In our issue for April 1, we printed on page 217, an article under the caption "Mutilators of Telegraphy and Telephony," written by Mr. F. M. Ewing, of Williamsport, Pa. The article has attracted considerable attention among our readers, and is being favorably commented on. Mr. I. D. Maize, of the Western Union Telegraph Company, Philadelphia, Pa., says he heartily endorses what Mr. Ewing says regarding "butchers of Morse," and offers some suggestions.

"If the sending operators," he says, "would only stop to consider for one moment the misery they are entailing on the receivers with their imperfect sending, they might be brought to realize the fact that a little better service would make it easier for the receiver. Many of them, however, will give the weight on their transmitting device another turn and do worse than before.

"A good receiver," he continues, "will never find fault with good sending, as it is a joy and a pleasure to receive when one is sure of every letter and word. This state of mind, however, cannot exist when the sending is by means of a transmitter. There is a vast difference in the sense of a message when one gets 'hold' for 'sold' or 'Shencer' for 'Spencer.' There are often single letters in a message and it is extremely difficult to tell whether the sender tried to make a 'p,' '6,' 'B' or '8.'"

"The receiving operator should be the judge of the sending and the sending operator should take heed if the receiving operator calls his attention to his deficiencies, if any exist."

Western Union Standard Window Signs.

The Western Union Telegraph Company is issuing, through its Engineering Department, specifications providing for uniform window lettering in all offices of the company where the Bell telephone system maintains public pay station service. The upper panels, reading "Western Union" will have a white translucent field on which will appear opaque blue letters. Below this will appear the joint office trade mark, which will be furnished in decalcomanias. The lower panels naming the different classes of service will consist of white translucent letters on an opaque blue field.

Twenty-four Hour Clocks in France.—A new system of measuring time will be inaugurated in the French railway, postal and telegraph services on June 1. The hours will be numbered from one to twenty-four from midnight to midnight. This new system will abolish the use of "a. m." and "p. m."

The Dick Patent Case.—The Supreme Court of the United States has declined to rehear the Dick patent case.

Mr. F. O. Nourse, district commercial superintendent, Western Union Telegraph Company, Richmond, Va., writes: "It gives me great pleasure to renew my subscription, first on personal grounds, and second because of the value of the paper."

Digitized by Google

Radio-Telegraphy.

Government Ownership of Wireless Systems.—Representative Berger, of Wisconsin, has introduced a bill in the House of Representatives at Washington, providing for the nationalization of the radio-telegraph systems.

New Marconi Directors.—John R. Sheffield, John L. Griggs and Kenneth K. McLaren have been elected directors of the Marconi Wireless Telegraph Company of America.

Mr. Marconi on the Witness Stand.—Signor Guglielmo Marconi was on April 25 a witness before the Senate committee investigating the "Titanic" disaster. He denied that the news of the sinking of the steamer was withheld by operators Bride and Cottam.

A Lesson Showing the Need of Wireless.—As a result of the burning of the steamer "Ontario" on Montauk Point, Long Island, recently, the New England Navigation Company is erecting a wireless station at Westerly, R. I.

Wireless Around the World Direct.—Signor Guglielmo Marconi states that he believes it will be possible in the near future to send a wireless message from New York completely around the world and be received by an instrument located in the same office with the transmitter, without any intervening relaying

Driven from His Wireless Post by Flames.—Herbert Ingalls, the wireless operator on the steamer "Ontario," which was beached on Montauk Point, L. I., recently, after being discovered on fire, stuck to his post until the flames destroyed part of the wireless equipment. He sent out the distress call before the flames crippled the apparatus.

Wireless Compass.—Signor Guglielmo Marconi has invented a so-called "wireless compass." Details of this apparatus have not yet been made public, but its general purpose is to enable navigators to determine the position of their ships in fog or stormy weather, by noting the direction from which wireless signals from shore stations and other ships are received.

Investigating Effect of Vegetation Upon Wireless.—Wireless tests are being conducted by the United States Navy Department, at Washington, D. C., Annapolis, Md., Philadelphia, Pa., and Norfolk, Va., to determine what effect vegetation has upon radio waves. The tests will consist of sending series of letters for a short period, followed by reports of the weather conditions. This will be done at irregular intervals each week under all kinds of weather conditions.

Simple Wireless Receiving Circuit.

Mr. Albert E. Peyton, of Fort Gibson, Alaska, has sent us a sketch of a simple wireless receiving circuit, a description of which, he thinks, may be of interest to wireless amateurs and experimenters. He uses a stove pipe for the aerial, and he has used, as well, for the purpose bed springs, a bracket lamp and a rifle in its rack in the same room. Mr. Peyton's office is about 600 yards from the wireless station at the Fort Gibson government post and he can, he states, hear the signals very plainly.

He uses an 80-ohm telephone receiver in series with the detector. The detector consists of a piece of silicon and a short length of fine steel wire which makes contact with the silicon, the lead connecting with the stove pipe.

The wireless plant at the Fort Gibson post is a 10-kw. quenched spark system of the Telefunken Company.

The Wireless Situation in the United States.—It was recently stated by a New York newspaper that the wireless patent situation in the United States is now "settled," but Mr. John L. Hogan Jr., points out that such is not the case. The Marconi Company, he says, is a party to some five patent suits at the present time, and is defendant in suits brought by the National Electric Signaling Company for infringement of three United States patents. Complete proofs have not been taken in any of these, and no patent of Marconi's has been broadly sustained by any United States court.

In addition to those above mentioned, he continues, numerous suits for infringements of Fessenden's basis patents have been brought against the Telefunken, Radio, North American, Wireless Specialty, and other companies. All of these are in process of litigation, and the outcome cannot be known for some time to come.

Effect of Atmosphere on Wireless Signals.

Mr. A. Esau describes in *Physikalische Zeitschrift*, his investigations on the effect of the condition of the atmosphere upon the damping of wireless telegraph signals. When the antenna wires are covered with hoar-frost or ice the damping is increased up to 200 per cent. In rain it increases up to 100 per cent., and when snow is falling up to 50 per cent. Fog causes very little change. The electrical conditions of the atmosphere causes changes up to about 20 per cent. Atmospheric disturbances increase with the increasing transparency of the air, with decreasing moisture, with increasing wind velocity, and with the formation of thunder clouds. They diminish with increasing cloudiness, mist and fog. They are more frequent at midday and at midnight. The maxima disturbances occur in June and August, with a secondary maximum in December. The winter months are quietest.

Wireless Telegraph Stations of the World.—The United States Navy Department has prepared a pamphlet giving a list of Wireless Telegraph Stations of the World. Copies can be obtained at the office of TELEGRAPH AND TELEPHONE AGE, New York, at 35 cents per copy.

Signal Corps Review.—The first company Signal Corps, National Guard, New York, will hold a music ride and review by Major-General J. F. O'Ryan at the armory at Seventh Avenue and Fifty-ninth street, New York, at 8 p. m., May 4.

The Telephone.

The headquarters of Mr. H. J. Pettengill, president Southwestern Telephone and Telegraph Company, have been transferred from Dallas, Tex., to St. Louis, Mo.

Telephone Regulation in the Southwest.—Mr. H. J. Pettengill, president of the Southwestern Telegraph & Telephone Company and of the other companies comprising the Southwestern group, advocates the establishment of corporation commissions in the various Southwestern states for the regulation of the telephone.

Mountain States Telephone & Telegraph Company.—The directors of the Mountain States Telephone & Telegraph Company have authorized the expenditure of approximately $2,250,000 for extensions and improvements during 1912. Of this sum, $500,000 will be spent on the new exchange in Salt Lake City, and about the same amount in extending and improving the service in the rapidly developing fruit districts in southern Idaho. The balance of the appropriation will be used in bettering the service throughout the territory covered by this company.

Cumberland Telegraph and Telephone Company.—The gross earnings of the Cumberland Telegraph and Telephone Company for the year ending December 31, 1911, were $7,372,661. Operating expenses amounted to $4,443,222, which, with charges and taxes of $637,208, left a surplus of $2,291,231. Out of this amount, dividends of $1,574,412 were paid giving a net surplus of $717,819. This is a slight decrease compared with the surplus of $832,856 in 1910 although in this year the gross business was less than in 1911. The total surplus is now $5,519,843.

Telephone Facts in the Census.—The recent United States Census reveals some interesting facts regarding the telephone service in the United States, among which the following may be enumerated: Eight million miles of wire added to American telephone systems in five years. Iowa, Nebraska, Washington, Nevada and California lead the States in number of telephones to population. Texas sends more messages per capita than New Jersey and Utah leads Pennsylvania. Cleveland has the greatest number of telephones to every thousand inhabitants; New Orleans the least. In Chicago the company has 60,000 requests daily for the time. The busiest hour for the telephone exchange is between 10 and 11 a. m.; busiest day in the year, the day before Christmas. Five office buildings in New York have telephones enough for a city of 100,000 people.

An Electro-Magnetic After-Dinner Speaker.—Members of the Yale Club, residing in Chicago, recently held a dinner at the Hotel Blackstone and listened to a speech by telephone from president Hadley at New Haven, Conn. Two direct wires were connected through from president Hadley's home in New Haven to the Hotel Blackstone in Chicago, with a telephone repeater at the latter point, in order that no word of the speaker's remarks might be lost. The diners, seated in groups of eight at small tables, listened through Western Electric watch-case receivers to a most interesting five-minute speech. Having finished speaking, president Hadley took up a receiver on the second or listening circuit and for over half-an-hour listened to the songs and cheers of the gathering. To president Hadley, therefore, belongs the unique distinction of having made the longest long-distance speech on record.

Changes in Southwestern Telephone Management.—Mr. H. J. Pettengill, president of the Southwestern Telephone and Telegraph Company, Dallas, Tex., has announced the following changes in the company's executive staff: C. A. Gates general superintendent of the plant department, has been appointed general manager. E. D. Nims becomes vice-president of the Bell Telephone Company of Missouri and the Pioneer Telephone and Telegraph Company of Oklahoma. Edgar S. Bloom becomes second vice-president of the Southwestern Telephone and Telegraph Company, with headquarters in St. Louis. J. P. Crowley becomes secretary of the Southwestern Company at Dallas. J. E. Farnsworth continues as first vice-president of the company, but is relieved of general management burdens in order to devote necessary time to the higher responsibilities of his position. Col. G. W. Foster has been appointed as his assistant.

Mr. Vail on Automatic Telephone Systems.

Mr. Theo. N. Vail, president of the American Telephone & Telegraph Company, being asked recently as to how extensively the automatic telephone would be used in the future, said that in his opinion the automatic and manual systems will both be used in the future, each to serve in its peculiar field. "We are not," he said, "building up our reserve with the idea that we may be compelled to abandon the manual system for the automatic. We could and would have adopted the automatic system long ago had we thought it practical for our needs.

"If the automatic operating cost were less than that of the manual system," he continued, " we would have installed it before this. As for other claims made for the automatic service, we are unable to see that they are well founded. There must be intelligence somewhere on the line in case anything goes wrong. Our system is automatic from the time you give your number to the operator, and we believe that in the great majority of cases the operator is an essential part of the system as serving to correct at once any trouble a subscriber may have. Finally, the automatic system does not make the work less for the subscriber, but on the contrary shifts the operator's duties to the subscriber. Undoubtedly, the automatic service will find a field of its own, but in my opinion it will never supplant the manual system any more than the wireless telegraph will supplant the wire telegraph for land service. It is not adapted to the needs."

Telephone Subscribers Agents for Western Union.

It was reported from Philadelphia recently, that the Western Union Telegraph Company was adopting an arrangement whereby certain telephone subscribers are made agents for the company, receiving 10 per cent. commission on all telegrams sent over the telephone wires, and that agents of the Department of Justice, are investigating the legality of the scheme under the anti-rebate law.

Mr. F. H. Bethell, vice-president of the New York Telephone Company explained that for some time it had been the custom to make the people in charge of many of the drug store, hotel and other telephone pay stations, agents of the company, with a commission interest in the receipts. The same idea, he explained, was now being tried to a limited extent with the telegraph company, the drug store people receiving the telegram, accepting payment, and, after telephoning it to the Western Union office, collecting their commission.

Chinese Telephone Students in the United States.

During the early part of 1911, the authorities of the Government Technical College at Shanghai, China, or Nan Yang University, as it is now known, feeling the growth of a national telephone system to be assured, took up with the Western Electric Company's representative in China the question of sending a number of the members of the graduating class in electrical engineering to the United States for training in that company's shops.

The necessary arrangements were quickly made and after graduation in July, 1911, three men, the first ever sent out by the University for such training, came to Chicago to the Hawthorne plant of the Western Electric Company, where they will engage in the practical study of telephony, in the company's student course. Following this, they will spend some time with one of the large operating telephone companies. Upon completion of their studies, they will return to their native land, where it is expected that they will be of material assistance in promoting and developing the telephone system of China.

Bell Memorial at Brantford, Ont.

The Bell Memorial, which is to be erected at Brantford, Ontario, the birthplace of the telephone, will be completed some time during the summer of 1913. The Bell Telephone Memorial Association at Brantford, under whose auspices the memorial is being prepared, plans also to purchase Tutela Heights, the family homestead at which Dr. Alexander Graham Bell experimented with his invention during his vacations.

The memorial proper is to be a statuary design of granite showing allegorical figures representing humanity sending and receiving messages. Between these figures which are so placed as to give the impression of great space between the speaker and listener, a flight of broad low steps leads to a large sculptured panel designed to show man discovering his power to transmit sound through space, and three floating figures representing the messengers, Knowledge, Joy and Sorrow. To the left of the large panel will be a portrait in relief of Professor Bell, modeled from life. On the back of the design are four pilasters between which runs a telephone line, and binding the whole is the line of the earth's curvature, expressing the world-wide use of the telephone.

Telephone Franchise in Ottawa.—The city of Ottawa, Canada, has given to the Bell Telephone Company a 5-year exclusive franchise, the company to pay $12,000 annually (against $5,000 formerly) and supply the city with 20 telephones free. The service rates are to remain the same —$45 for business telephones and $25 for residence telephones.

Canadian Telegraph Lines.

The following figures relating to the operation and equipment of the various Canadian telegraph companies in the year 1910-11 are published in the *Railway and Marine World*:

The Dominion government owns 8,406 miles of telegraph line and cables, 8,150 miles being land lines. There are 603 offices, and 249,915 messages were sent in the year. The expenditure was $432,970.04, and the revenue $169,585.15, a deficit of $263,384.89.

The Canadian Pacific Railway Telegraphs operated 12,257 miles of telegraph line, with 76,175 miles of wire, sending 3,431,493 messages. It has 1,372 offices.

The Great North Western Telegraph Company operated 11,234 miles of pole lines, with 50,092 miles of wire, sending 2,907,495 messages, and has 1,183 offices.

The Western Union Telegraph Company had 2,639 miles of pole lines with 11,024 miles of wire, sending 551,764 messages, with 217 offices.

The North American Telegraph Company operated 605 miles of line, with 783 miles of wire, and sent 38,015 messages, with 83 offices.

The Grand Trunk Pacific Railway operated 1,699 miles of pole lines, with 5,081 miles of wire, sending 71,154 messages with 73 offices.

The Algoma Central Railway had 130 miles of line, 174 miles of wire, and sent 3,639 messages with four offices.

The Temiskaming & Northern Ontario Railway had 265 miles of pole line and 1,865 miles of wire, sending 131,106 messages with 22 offices.

The total mileage of pole line owned by all the companies in Canada was 28,729, and the line mileage operated by telegraph, telephone and cable companies was 145,997. Messages taken and delivered over all these lines, not including press messages, 7,134,665, and total number of offices 2,934.

New York Electrical Show.—The New York Electrical Exposition and Automobile show of 1912 will be held at the New Grand Central Palace, New York, October 9 to October 19.

Testing on Railroad Telephone Circuits.

BY K. W. ENDRES, NEW YORK.

(*Continued from page 252, April 16.*)

INSTALLATION TESTS.

After the line and drop wires have been installed on a telephone train dispatching circuit, it is desirable to make sure that these are in good shape and perfectly clear before going ahead installing the apparatus at the stations. This can best be done by wiring a telephone set across each end of the line and talking. If the line is in trouble, due to grounds, crosses, or bad leaks, this will be revealed either through conversation being impossible, noise on the line, or both. If the line is quiet and conversation clear and loud, it is probably in first-class condition. It would also pay, if there is time, to bridge a telephone receiver across the line somewhere near its middle point and listen there for a day or so, reporting all noise heard.

If switching panels or test boards are installed, the line can be opened at successive points and by listening on either side of the break, it can be found in which direction the noise exists. Thus it can be closely located. If testing equipment is not installed, it is then necessary to send out a man to hunt the trouble. This will generally appear either in the transpositions, which may be crossed, or in the guy wires which may have become slack and so ground the line when they sway. Crossed transposition wires should be cleared and the guys tightened in such cases. Trouble should also be looked for at bridges. If it appears at such points, it may be advisable to run circular loom cable under the bridge. Twisted pair is not especially satisfactory for such service, owing to the fact that the insulation is quickly destroyed by the locomotive gases. Open circuits, of course, should not appear on a newly constructed line.

Readings should be made on the line with a voltmeter and milliammeter. The resistance of the circuit can be calculated from wire tables giving the size of wire and its resistance per mile. Now, take a battery of dry cells and measure its voltage (using about twenty cells in series); then make a loop of the line by short-circuiting its distant end and apply the battery through the milliammeter. If the actual current flow does not agree closely with the calculated current, it is an indication of trouble. The current reading which should be obtained on the milliammeter may be figured as follows:

$$\text{Current} = \frac{\text{battery voltage}}{\text{loop line resistance}}$$

A much higher value than this would indicate a short circuit or cross on the line, the amount of excessive current depending on the distance away of the short or the resistance of the cross. A much lower value would indicate high resistance joints or poor connections somewhere; this would also show in the poor transmission of speech obtained. A zero reading would indicate an open circuit. Grounds on either side of the line can also be detected by a milliammeter. Have the line in its normal condition (before installing way-station apparatus) then ground one side of the battery and apply the other side to one line wire through the milliammeter. There should be no reading unless there is a ground on the line. A slight deflection of the needle would indicate faulty insulation. Do the same thing to the other wire of the circuit.

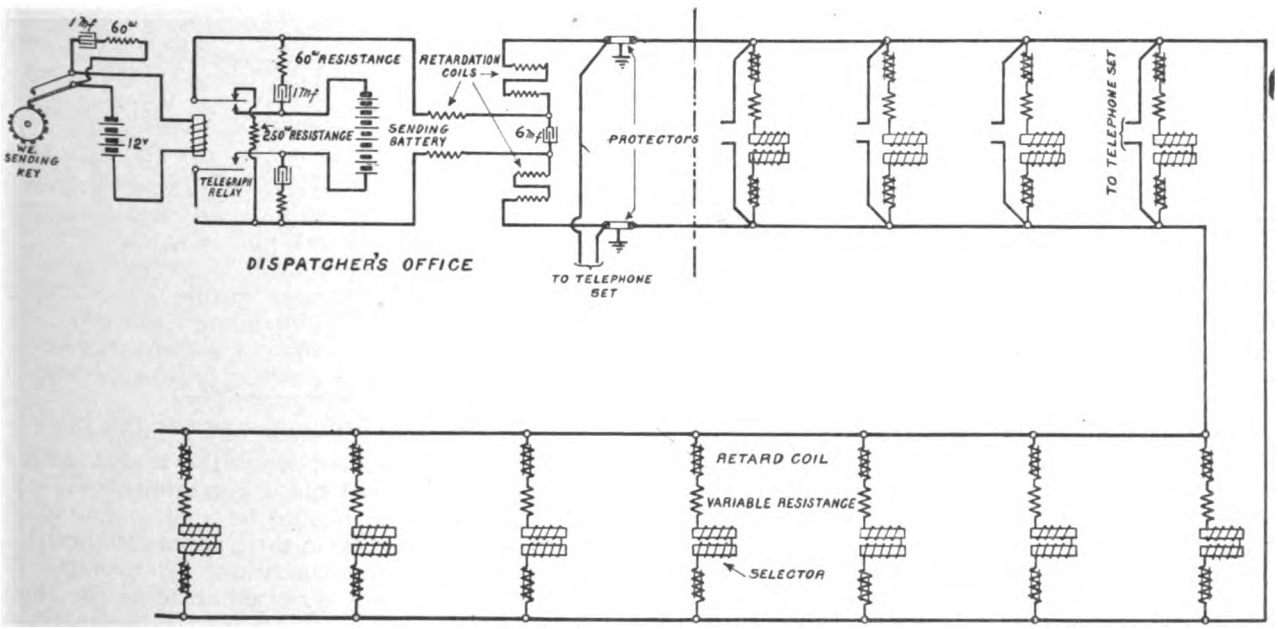

FIG. 6.—WESTERN ELECTRIC TRAIN DISPATCHING CIRCUIT.

Digitized by Google

TRAIN DISPATCHING CIRCUITS.

After the dispatcher's and way-station equipments have been installed on a train dispatching circuit, we have a condition which is entirely different from the ordinary telephone circuit; in other words, there are a number of permanent high resistance and high impedance bridges across the circuit. These are the selectors, and the resistance of these varies from 3,800 to 16,000 ohms according to the type used. A schematic illustration of the telephone train dispatching circuit is shown in Fig. 6.

It is obvious from this that the ordinary methods of testing telephone circuits are not applicable to one of the train dispatching type. This is for the reason that practically all of the testing methods employed on the standard commercial circuits are dependent on having the wires free and not equipped with bridged resistances. Accurate measurements on the line are, therefore, to a great extent impossible, but instrument readings, with a little practice, will give very close results and enable a man familiar with his circuit to locate trouble to the nearest way-station. This is as close as is desired, and is as close as now obtained in testing on telegraph wires.

LINE TROUBLES.

It has been found by experience that 90 per cent of the troubles occurring on telephone train dispatching lines are not in the apparatus nor instruments, but are on the line itself and for this reason trouble should be looked for here first of all. The following is a list of some of the possible troubles on the line which may cause signaling failures at the way-stations:

1. The line may become short-circuited, due to crossing of the wires or by lightning fusing the protectors together.
2. The line may become open, in which case the trouble can be easily located by calling the various stations until the neighborhood of the break is reached.
3. A loose joint in the line causes a loud grating noise in the dispatcher's receiver while he is calling. A very loose swinging joint may affect the operation of the selectors.
4. A swinging cross on the line causes a loud grating noise in the receiver when the dispatcher is calling, and may also cause a selector to fail to operate, or the wrong one to respond.

METHOD OF LOCATING TROUBLE.

One very satisfactory way of locating opens and short circuits on the telephone line is by the use of a milliammeter. This instrument should be connected in series with one side of the circuit. A convenient way of doing this is to place the milliammeter between the contacts of the telegraph sending relay and the line, as shown in Fig. 7.

Readings should then be taken with the line in good working condition on a normal day, first with all the stations connected across the circuit. The current flowing in this case should approach closely the normal current taken by each selector multiplied by the number of stations. Large variations from this should be looked into, as they are an indication of trouble on the line. A zero reading would be obtained only in case of a break in the line between the dispatcher and the first way-station. A ground on either side would also show up in testing either wire, only there would be a much heavier current flow when testing the side which is actually grounded. This is, of course, obvious, due to the resistance of the bridges through which the current would have to flow to ground on the opposite side of the line.

This normal reading having been obtained, starting at the most distant end of the line from the dispatcher, each successive station in turn

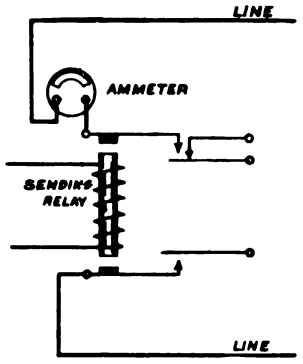

FIG. 7.—LOCATION OF AMMETER FOR TESTING.

should be disconnected from the circuit and a reading made under these conditions. At the same time, the line should be short-circuited at each successive station in turn, and a reading likewise made under this condition. The result will be two tables giving a current reading for each station when the line is open just beyond that station and when the line is short-circuited at that station. These tables should be kept in an available place, preferably at the dispatcher's desk.

In case of trouble on the train dispatching circuit, which is not obvious in the dispatcher's office, the first move would be, therefore, to make a current reading on the line. The value of the current obtained from this reading should be compared with the values listed on the table mentioned, and would, therefore, give a quick indication as to where the probable location of the trouble is, as well as its nature.

SHORT CIRCUITS.

A short circuit may occur at any point on the line. When it happens at some point near the dispatcher's office, it is impossible for him to ring any of the bells on the line. When the short circuit is a long distance from the dispatcher's office, he may be able to ring the stations near his office, but he will be unable to ring any stations in the neighborhood of the cross.

A short circuit on the line near the dispatcher's office causes the contacts of the sending relay to spark more than they do when the short circuit is near the far end of the line.

Digitized by Google

TESTS IN DISPATCHER'S OFFICE BATTERIES.

In the operation of the selectors, two sets of batteries are used at the dispatcher's office; namely, a local battery which operates the sending relay and is controlled by the contacts on the sending key, and the other, the main line battery which operates the selectors at the way-stations and is controlled by the contacts of the sending or transmitter relay. These two batteries and their relations to the circuit are shown on the circuit diagram in Fig. 8.

LOCAL BATTERY FOR OPERATING SENDING RELAY.

This battery, as Fig. 8 shows, is controlled by the contact on the sending keys, which are mounted in the cabinet on the dispatcher's desk, and it operates the sending or transmitter relay. The best results are secured if the current (in the winding of the sending relay) supplied by this battery does not fall below 0.25 amperes. The resistance of the sending relay is approximately thirty-one ohms, and if the battery gives a voltage of eight to nine volts (measured when the relay is drawing current) 0.25 ampere will be secured. This battery is usually made up of two sets of eight dry cells connected in series multiple as shown in Fig. 9. The method of testing this battery is also shown in this figure.

The voltmeter should be read when the contact on the sending key is held closed and the batteries are sending current through the relay.

MAIN LINE BATTERY.

The function of the main line battery is to supply current to the line to operate the selectors.

The voltage of the main line battery may be too low to send sufficient current over the line to operate the selectors. When the batteries have been in use for a long time, the voltage not only drops, but the internal resistance of the battery increases thus cutting down the current sent out over the line to operate the selectors. A voltmeter placed directly across the terminals of the battery when the sending relay armature is held up so that a steady current can flow out on the line, will tell whether the voltage is low. In measuring the voltage in this way, as well as on the local battery previously described, it is very essential that the battery be supplying current to the line (or the sending relay) at the time the voltage is read. When a dry battery is not supplying current to the line, the voltmeter reading may be much higher than when current is flowing on the line, on account of the internal resistance of the battery.

In the absence of a voltmeter, the dry cells can be tested individually with a good battery gauge.

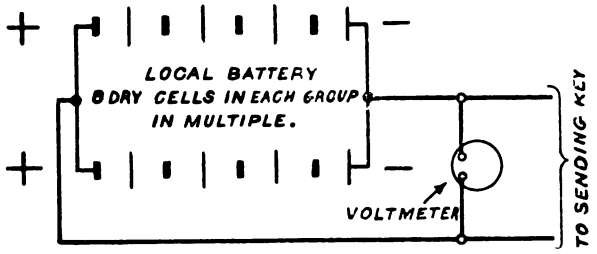

FIG. 9.—WIRING OF SENDING RELAY BATTERY. DISPATCHERS OFFICE.

When a battery gauge is used to test the cells individually, it is not necessary to have current flowing out on the line.

The voltage of the main line battery is determined for each particular installation. It should not be allowed to drop more than 12½ per cent. below its normal value, as originally calculated, for the particular circuit in question.

CIRCUIT DATA.

When a telephone train dispatching installation is cut into service, the maintenance man who is to care for this circuit should be furnished with the following information which should be kept on file at the dispatcher's office.

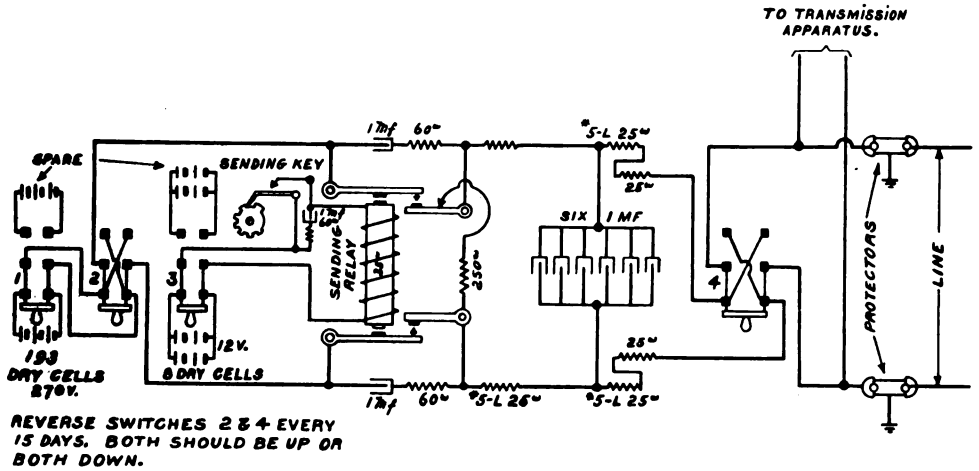

FIG. 8.—CIRCUIT DIAGRAM.

MAIN LINE BATTERY.

This battery is located at .....
It consists of ..... dry cells connected in series.
Battery voltage .....

This battery is controlled by the contacts of the sending relay shown in the circuit diagram (See Fig. 8).

With the voltage at ....., the current in each selector is ..... milliamperes.

Digitized by Google

Patches may be put in the dispatcher's line, provided they do not reduce the current per selector to below ..... mills, which is the least current upon which the selectors will operate.

As the cells drop off in voltage with use, more can be added from time to time to retain the voltage at its normal figure.

The voltage of the battery should be measured when the current is flowing out on the line.

A dry battery on open circuit or when it is only supplying current to the voltmeter across its terminals will often indicate high voltage, but the voltage will fall to a very low value (if the internal resistance of the battery is high) when the circuit is closed and it is supplying current to the line.

In reading the voltage, place the voltmeter leads directly across the battery leads and not across the line.

SENDING KEYS.

The function of the sending keys is to control by their contacts the transmitter or sending relay which, in turn, controls the battery current for operating the selectors. The operation of these keys in the dispatching circuit is shown in Fig. 8. Trouble in these keys will ordinarily occur in the adjustment of the springs which are operated by the toothed impulse wheel, and it is a simple matter to remove a key and adjust these at any time. If the keys become noisy, a little graphite applied to the gear wheels will ordinarily care for this satisfactorily.

SENDING RELAY.

The sending or transmitter relay controls the current operating the selectors, and it is clearly shown in Fig. 8. This sketch also shows the method of arranging the reverse switches 2 and 4 at the dispatcher's office so as to protect the relay contacts from undue wear. By reversing the switches 2 and 4, the direction of the current in the relay contacts is changed and they will wear a much longer period without cleaning.

This relay is adjusted in somewhat the same manner as a telegraph relay. The best all round results are secured when the contacts of this relay are so adjusted that the current is kept on the line about 50 per cent. of the time and off about 50 per cent. of the time when the sending key is causing the selector to step up. If the armature of the sending relay is too close to the pole pieces, it is evident that the current will stay on the line too long and the selector or armature cannot fall back so as to make the next step. Also if the armature of the sending relay is too far from the pole pieces, current will not stay on the line long enough.

To determine whether the sending relay is keeping the current on the line about 50 per cent. of the time during the stepping up of the selector, it is only necessary to put an ammeter on the line as shown in Fig. 10, and turn one of the higher numbered keys. The reading of the ammeter while the sending key spring is passing over the stepping teeth should be 50 per cent. of the steady reading obtained with the sending key spring held permanently closed. In case the ammeter should not read approximately 50 per cent. of the steady value, the local battery should be checked and the sending key should be checked so as to make sure that the fault is not in the local battery nor the key before adjusting the relay.

If the ammeter reading is found to be 40 per cent. of the steady value, this means that the pole pieces of the relay should be set slightly closer to the armature so that the contacts will be closed a little longer. If the relay is set to read about 50 per cent. as described, when the local battery controlling the relay is new, it will run a little below 45 per cent. when the local battery is nearly run down. It is not necessary, however, to readjust the relay on account of this. From time to time an ammeter should be connected as has been described, and an inspection made in order to insure the best results on the circuit.

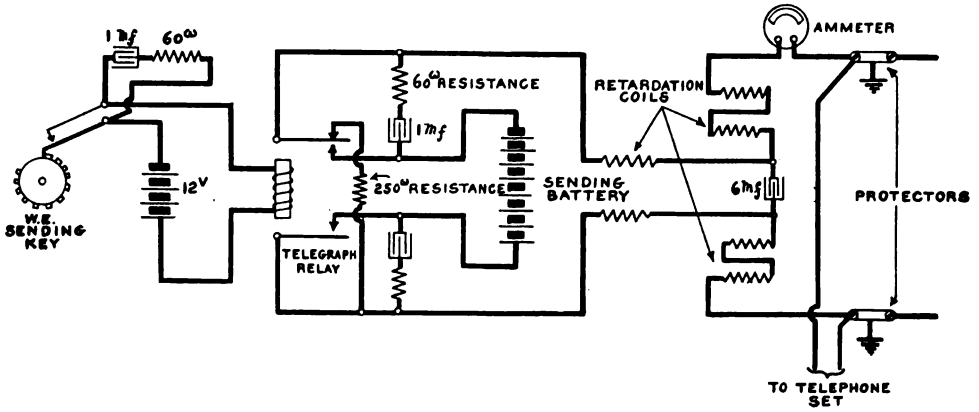

FIG. 10.—TERMINAL TESTING ARRANGEMENTS ON WESTERN ELECTRIC DISPATCHING CIRCUIT.

If the sending relay sparks excessively while sending, too much current is being sent out, which indicates that the line is crossed. The dispatcher will be unable to call or talk to stations beyond the cross, neither will he be able to call or talk to the first two or three stations on his side of the cross.

NOISE.

If the noise is excessive while sending, and the sending relay sparks badly, the condenser in the dispatcher's telephone circuit (inside the desk set box) or the condensers which are bridged around the local contacts of the sending relay, may be broken down.

(To be continued.)

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

May 1, 1912.

Wireless in the Titanic Disaster.

Again wireless telegraphy has demonstrated its great value to shipping interests, and had it not been for the wireless it is quite conceivable that the 700 or more passengers rescued from the ill-fated "Titanic" might also have been lost, in addition to the hundreds of unfortunates who went down with the steamer to watery graves.

The story of the wireless in connection with this, the greatest of sea disasters is an intensely interesting one. The accounts of the work of the operators on the "Titanic" and on the steamer "Carpathia," which rescued the seven hundred passengers from life boats, give evidence of their coolness and bravery under circumstances which test men's souls. While all was excitement on the ill-fated steamer, the two operators stuck to their posts to the last and did all that was within their power to do. When nothing more could be done, Captain Smith, of the "Titanic," told them they had done their duty, and were at liberty to save themselves. They then extended a helping hand in saving passengers, and were among the last to leave the ship as she went down.

Several most valuable lessons may be drawn from the experiences attending this awful disaster, and the fact that stands out most prominently is that it should be imperative that all passenger steamers carry two wireless operators at least, the object being, of course, to have some one listening-in every moment of the time. It was by the merest chance that the operator on the "Carpathia" learned of the "Titanic's" distress. He had been absent from his instrument for a few minutes, and, on returning, was preparing to retire for the night when, by chance, he put on his telephone headpiece. It was then that he heard the "Titanic's" distress call. Had he retired without listening-in as he did, it is probable that the results would have been much worse than they were, because the "Carpathia" would have been ignorant of the disaster and would not have gone to the rescue.

Some months ago, when the steamer "Prinz Joachim" was wrecked in the West Indies, there was much loss of time in going to the rescue, because the wireless on some of the stations in the vicinity was unguarded. Mr. W. J. Bryan, who was a passenger on the wrecked steamer, then suggested the importance of having a wireless operator on duty at all times, and the force of this suggestion is emphasized by the experience on the "Carpathia." Another instance showing the great necessity of such a provision is furnished in the case of the steamer "Parisian" which was at the time in the neighborhood of the "Titanic." The "Parisian's" operator had been in communication with the "Titanic" before he retired on Sunday night, after being on duty for eighteen hours. Nothing was known of the disaster on the "Parisian" until the operator resumed duty on Monday morning, when it was too late to be of any assistance.

Mr. Harold Bride, the surviving operator of the "Titanic," who was rescued by the "Carpathia" and afterwards assisted the worn-out operator on the latter steamer, severely arraigns the wireless operator on the United States scout cruiser "Chester," and charges general incompetence. Similar charges have been made against navy wireless operators before, and if there is any truth in them, the navy authorities should see to it at once that none but first-class operators be employed on the ships of the navy. The charge as far as the "Chester" is concerned, however, has been denied by the officers on that cruiser, and an investigation will probably be made.

Apart from all the discordant circumstances attending the awful event, the bravery and sound judgment of the wireless operators concerned stand out in bold relief, and they are deserving of the greatest honors that the world can bestow upon them. They are heroes in the broadest sense of the term, and the world loves a hero.

What is the Matter with the Men.

It was recently announced that women wireless operators were being employed on Pacific-coast steamers in preference to men, the alleged reason being that "men were not always satisfactory." What is the matter with the men?

Up to within the past fifteen or twenty years, men in civilized countries, have done the world's work, but women have in late years entered into competition with them in practically all lines of business with the result that men have, in many instances, been crowded out. The time may soon come when men will be compelled to do the work formerly performed by women, such as feeding babies, if there are any babies; family cooking and washing. If they do not do this work, who is to do it, while the wives, sisters and other female relatives are at work earning bread and butter for the family?

Digitized by Google

Some day we may see women at the head of large industrial concerns, bossing the present male bossers. The day of man as the main support of the family seems to be approaching the end. In the telegraph field, women are crushing the youthful male blossoms to earth, and we may some day see a woman at the head of the great telegraph and telephone corporations. In the telephone industry, they monopolize certain departments of the work, and when they reach the point where they think they know as much as men do, the males will have to surrender to their might.

It will be the men's turn then to fight for their rights, and instead of suffragettes, we will have suffering "gents."

Government Ownership of Telegraphs and Telephones in England.

The financial statement of the postmaster-general of Great Britain for 1910-11, was presented to Parliament recently, and, for the information of advocates of government ownership of the telegraphs and telephones in this country, we reproduce the following abstract of the statement as found in the London *Electrical Review*. The net revenue of the telegraph service was £5,121,342 and the expenditure £6,085,166, showing a deficiency of £963,824—the largest deficit ever recorded. The amount received in royalties, mainly from the National Telephone Company, was £342,542, and the amount paid to cable companies, foreign countries, etc., was £781,487 (deducted from the gross revenue). Of the expenditure, salaries and other working costs, amounted to £4,721,158, and items of the nature of capital outlay to £1,036,321. The total expenditure, apart from the latter, was £5,048,845, or £72,497 less than the total receipts. The figures are exclusive of the capital expenditure on the purchase of the telegraphs, etc., which amounted to £10,129,687; the interest paid on this account was £271,691, which brings up the total deficiency on the telegraphs for the year ended March 31, 1911, to £1,235,515.

The capital expended on telephone purposes to March 31, 1911, was £11,130,327. The total capital expended on both telegraphs and telephones, including sums spent on extensions, etc., is given as £29,293,289.

The total deficiency in the telegraph account from the commencement is £19,821,381; excluding items of the nature of capital from the expenditure, the deficiency is reduced to £7,942,226, but in this no charge is made for interest on capital expenditure not provided by the issue of stock or the creation of annuities.

The total expenditure on trunk telephone lines was £5,337,725, and on exchanges £3,913,204 in London, £1,691,619 in the provinces. The telephone revenue was £1,595,787, and expenditure £1,146,629, leaving a balance of £449,158, which, added to the royalties mentioned, fell short by £262,187 of the amount necessary (£1,053,887) for the repayment of principal, interest, etc., on outstanding loans.

International Association of Municipal Electricians.

The seventeenth convention of the International Association of Municipal Electricians will be held in the Hotel Jefferson, at Peoria, Ill., August 26 to 30.

The International Association of Municipal Electricians is composed of municipal electricians from all parts of the United States and Canada, as well as from Cuba and South America. Its objects are the acquisition of experimental, statistical and scientific knowledge relating to the constitution, equipment and operation of fire and police telegraphs, light, heat and power systems, and the diffusion of this knowledge among the members of the association with a view of improving the service and reducing the cost thereof, and the establishment and maintenance of a spirit of fraternity among its members.

The annual conventions have proved to be the source of much benefit to the municipalities represented by the members of the association and to the country at large through the information given out in the form of papers and discussions. These papers relate to matters of great importance to municipal electricians and their work, and are of the most practical kind, because they are prepared by practical men.

The officers of the association are: John W. Kelly, Jr., chief of electrical bureau, Camden, N. J.; vice-presidents, John Craig, superintendent fire alarm, Toronto, Ont.; W. L. Riehl, superintendent of electricity, Indianapolis, Ind.; secretary, Clarence R. George, city electrician, Houston, Tex.; treasurer, Clark E. Diehl, superintendent fire and police telegraph, Harrisburg, Pa. Chairman Executive Committee, W. E. Wolgamott, city electrician, Peoria, Ill.

Electrical Instruments and Testing.

Every one connected with the telegraph and telephone service should know how to test lines and also be familiar with the instruments used in such work. It does not require much study to learn the mechanical operations of this important branch of the service, but of course a knowledge of electrical and mechanical principles involved in the design and construction of the instruments, and of the principles involved in measurements is the source of deep and never-ending pleasure to the ambitious student.

An excellent book on this subject, intended for the practical man, is "Electrical Instruments and Testing," by Norman H. Schneider, with new chapters on testing wires and cables and locating faults, written by Jesse Hargrave, division superintendent of the Postal Telegraph-Cable Company, Atlanta, Ga.

The price of this book is $1.00 and copies can be had of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York. Any other book on telegraph, telephone or general electrical subjects can be obtained at the same place.

Course of Instruction in the Elements of Technical Telegraphy—XIV.

(*Copyrighted.*)

(*Continued from page 246, April 16.*)

[We began in our issue for October 16, 1911, the publication of a course of instruction in technical telegraphy. The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and is divided into chapters, following one another in logical order.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.]

Derived Circuits.

Resistance, we have seen, is the obstacle which a circuit offers to the passage of the current.

Conductivity is the opposite; it is the facility with which the circuit transmits or conducts the current.

If a circuit have 2 ohms resistance, its conductivity is represented by ½; if the resistance be increased to 4 ohms the conductivity will only be ½ as much as before, or ¼.

As the resistance of a circuit increases, therefore, the conductivity decreases, and *vice versa*, as the conductivity increases, the resistance decreases.

Fig. 2 shows a derived circuit of two branches, A and B.

It is evident that, on account of the increase in conductor area, two conductors such as A and B (Fig. 2), connected in parallel, conduct the current more readily than would one alone; that is, their joint or combined conductivity is greater than the conductivity of either A or B alone. It follows that the combined or joint resistance of A and B must be less than the resistance of either single branch.

If the separate resistances of the two branches are equal, their joint resistance is equal to one-half of one of the separate resistances. Thus, in Fig. 2, the resistance between X and Y is the joint resistance of A and B, and equals 25 ohms, since A and B have 50 ohms resistance each.

When the separate resistances are unequal, the joint resistance is equal to the product of the separate resistances divided by the sum of the separate resistances.

Example: Branch A = 25 ohms, branch B = 50 ohms, find their joint resistance.

Solution: $\frac{25 \times 50}{25 + 50} = 16\frac{2}{3}$ ohms.

When there are more than two branches, the joint resistance may be found as follows:

Reduce the respective resistances of the branches to fractions having 1 for a numerator, and divide 1 by the sum of the fractions.

Example: Three branches of 5, 10 and 20 ohms, find their joint resistance.

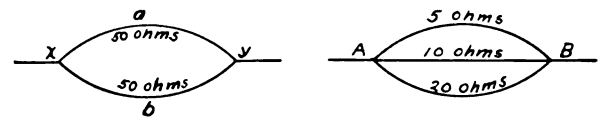
Solution: Reducing to fractions with numerator 1, $\frac{1}{5}$, $\frac{1}{10}$, $\frac{1}{20}$.

Finding the sum of the fractions, $\frac{1}{5} + \frac{1}{10} + \frac{1}{20} = \frac{7}{20}$.

Dividing 1 by $\frac{7}{20}$, $1 \times \frac{20}{7} = \frac{20}{7} = 2\frac{6}{7}$ ohms.

This method for determining the joint resistance is obtained as follows:

A resistance of 2 ohms represents a conductivity of ½; a resistance of 4 ohms a conductivity of ¼; and so on; therefore to find the conductivity corresponding to any given resistance, divide 1 by the resistance. Similarly, a conductivity of ½ repre-



FIGS. 2 AND 3.—TWO AND THREE-BRANCH CIRCUITS.

sents a resistance of 2 ohms, so to find the resistance corresponding to any given conductivity, invert the conductivity.

In the example the resistances being 5, 10 and 20 ohms, the corresponding conductivities are $\frac{1}{5}$, $\frac{1}{10}$, $\frac{1}{20}$.

The joint conductivity is the conductivities of all the branches added together.

Thus, $\frac{1}{5} + \frac{1}{10} + \frac{1}{20} = \frac{7}{20}$ = joint conductivity.

The joint resistance is the opposite of joint conductivity, or $\frac{7}{20}$ inverted, hence $\frac{20}{7} = 2\frac{6}{7}$ ohms = joint resistance.

Where the branches have equal resistances as in Fig. 2, the current divides equally between them. If a current of 2 amperes is flowing in the main circuit, 1 ampere will flow through each branch.

When the branch resistances are unequal, the current in any branch may be determined by the formula $\frac{E}{R} = I$, where E is the difference of potential between where the branches divide and where they unite, and R is the resistance of the branch in question.

Example: A derived circuit (Fig 3) has three branches of 5, 10 and 20 ohms resistance, find the current in each branch when there is a fall of potential of 5 volts between A and B.

Solution: Taking the 5 ohm branch first, $\frac{E}{R} = I$.

or $\frac{5}{5} = 1$ ampere = current in 5 ohm branch.

In the 10 ohm branch, by the same equation, $\frac{5}{10} = .5$ amp.

Similarly, in the 20 ohm branch the current is .25 ampere.

The total current, or the current flowing in the main circuit, is the sum of the currents in the branches; or 1 + .5 + .25 = 1.75 amperes.

It will be seen from the foregoing that the current divides inversely as the respective resistances

Digitized by Google

of the branches. In the first branch the resistance is 5 ohms and the current 1 ampere. In the second branch the resistance is double that of the first, the current is consequently only one-half, or .5 ampere. In the third branch the resistance is double that of the second, and the current therefore one-half its former value, or .25 ampere.

Since Ohm's law, $\frac{E}{R} = I$, gives the current in any branch of a derived circuit, the resistance of any branch and the fall of potential between the dividing and uniting points can also be found provided two of the quantities be known, for $\frac{E}{I} = R$, and $IR = E$.

(To be Continued)

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. The review of Maver and Davis' book. "The Quadruplex," was completed in our issue for February 16, and the next book to be taken up and treated in like manner is "Electrical Instruments and Testing," by Norman H. Schneider, with chapters on testing wires and cables and locating faults, by Jesse Hargrave, a well-known and capable electrical engineer. These subjects will no doubt prove of great interest to students, as they are timely and important, and each student should have a copy of the book at hand in order to follow intelligently the study of the subjects under consideration.]

What is a glass slab resistance and how is it made?

Can plumbago or pencil lead be relied upon to give invariable resistance?

In testing is it desirable to allow the entire current to flow through the galvanometer coil?

What is the purpose of a shunt?

What are the ratios of the shunts to the galvanometer?

Are the shunts fixed or adjustable?

When the ratio of the shunt to the galvanometer is one-ninth, how much current flows through the galvanometer; and how much flows through it when the shunts are one-ninety-ninth and one hundred and ninety-ninth?

What is meant by the multiplying power of a shunt?

If one-tenth of the current flows through the galvanometer and nine-tenths through the shunt, what is the total value of the current in the circuit as indicated by the galvanometer reading?

How is the true value of the current in the circuit ascertained from the galvanometer reading?

How can the necessary resistance of a shunt to be used with a certain galvanometer be found? State the rule.

If a galvanometer has a resistance of 2,000 ohms and it is desired to pass one-fifth of the current through it, what is the resistance of the shunt?

What is the formula used to obtain this information?

How is the multiplying power of a shunt ascertained?

Calculate the multiplying power of a shunt of 1,000 ohms used in connection with a galvanometer of 10,000 ohms.

Mr. Marconi's Lecture Before the New York Electrical Society.

Mr. Guiglielmo Marconi delivered an interesting lecture before the New York Electrical Society, April 17, on "Recent Developments in Wireless Telegraphy." He outlined the early work leading to the discovery of the principles upon which the production and detection of wireless messages depend, giving full credit to Maxwell, Ampère, Faraday and Hertz. The advantageous features of tuning the interrelated circuits so as to possess the same inherent natural vibratory period, and employing loose electromagnetic coupling between the mutually related circuits in order to avoid the production of detrimental superposed vibrations was not discussed. He expressed the opinion that no other single development in wireless telegraphy equalled the demonstration in 1901 that the curvature of the earth does not of itself tend to limit the distance of transmission of ether waves used in wireless communication, although it places a definite limit to the transmission of ether waves visible to the eye.

Mr. Marconi mentioned the fact that the ultraviolet rays in sunlight act on wireless waves just as does fog on light waves, the effect being greater the shorter the wave-length. On this account messages can be sent more easily at night than during the daytime and in cloudy weather than in clear sunlight. It has been noted that the damping effect of sunlight is even greater when either the sending or the receiving station is in darkness than when both are in sunlight, this result being due to the refraction of the waves at the surface separating darkness from sunlight. The fact that messages can be sent more freely over sea than over land is attributable to the greater and more uniform electrical conductivity of the surface of the ocean compared with the land surface.

In closing his lecture, Mr. Marconi stated that nature has provided in wireless-telegraph phenomena both advantages and disadvantages, the advantages always outweighing the disadvantages in connection with the most urgent communications. Under the conditions existing when communications are most desirable and difficult to obtain in any other way, namely, night-time, foggy weather, over troublesome seas, wireless telegraphy is at its very best in every respect.

On Prof. M. I. Pupin's motion, Mr. Marconi was elected an honorary member of the society, and in seconding the motion, Mr. Frank J. Sprague credited Mr. Marconi with saving the lives of from 700 to 800 persons rescued from the ill-fated "Titanic" by means of wireless telegraphy. Mr. Marconi was visibly affected by this compliment.

Digitized by Google

Wireless Telegraphy in the Titanic Disaster.

The entire civilized world was shocked beyond expression by the news of the awful calamity which befell the new steamer "Titanic" bound for New York, from Southampton, England.

The "Titanic," which was the largest and most magnificently fitted-up steamer afloat, and was on her first trip to New York, collided with an iceberg off the Banks of Newfoundland on Sunday night, April 14, and soon afterward sank in water over two miles in depth carrying to their death over 1,600 passengers and crew. Many of the lost passengers were prominent citizens of New York and other places in the United States. The tragic event has no parallel in history and has cast a gloom over the entire civilized world.

The story of the part played by the wireless telegraph in the disaster as told in the *New York Times* of April 19 by Mr. Harold Bride, the surviving wireless operator of the "Titanic" is one of thrilling interest.

Considerable criticism was indulged in by the newspapers because the wireless operator on the steamer "Carpathia" carrying the "Titanic" survivors refused to answer calls and questions from the scout cruiser "Chester" which had been sent out by the United States Government to render what assistance it could. Mr. Bride after being rescued and taken on board of the "Carpathia," assisted the "Carpathia" wireless operator in his work, and explained the "Chester" matter in a way that does not reflect any credit upon the naval wireless operator on that vessel.

"The wireless operators on the 'Chester,' he said, 'got all they asked for. And they were wretched operators. They knew American Morse but not Continental Morse sufficiently to be worth while. They taxed our endurance to the limit. I had to cut them out at last, they were so insufferably slow, and go ahead with our messages of grief to relatives. We sent 119 personal messages April 19 and 50 April 18."

Mr. Bride then continues:

"When I was dragged aboard the 'Carpathia' I went to the hospital at first. I stayed there for ten hours. Then somebody brought word that the 'Carpathia's' wireless operator was 'getting queer' from the work.

"They asked me if I could go up and help. I could not walk. Both my feet were broken or something, I don't know what. I went up on crutches with somebody helping me.

"I took the key and I never left the wireless cabin after that. Our meals were brought to us. We kept the wireless working all the time. The navy operators were a great nuisance. I advise them all to learn the Continental Morse and learn to speed up in it if they ever expect to be worth their salt. The 'Chester's' man thought he knew it, but he was as slow as Christmas coming.

"We worked all the time. Nothing went wrong. Sometimes the 'Carpathia' man sent and sometimes I sent. There was a bed in the wireless cabin. I could sit on it and rest my feet while sending sometimes."

Mr. Bride told of his duties on board the "Titanic." He and J. G. Phillips were the wireless operators, one being on duty while the other was off.

"There were three rooms in the wireless cabin," he said. "One was a sleeping room, and one a dynamo room, and one an operating room. I took off my clothes and went to sleep in bed Sunday night. Then I was conscious of waking up and hearing Phillips sending to Cape Race. I read what he was sending. It was traffic matter."

Mr. Bride was urging Phillips to go to bed when the captain put his head in the cabin and said: "We've struck an iceberg." Ten minutes afterwards the captain ordered the wireless call for assistance, and Phillips began to send "C. Q. D." The call was heard by the steamer "Carpathia," whose captain immediately headed his steamer for the "Titanic."

"Every few minutes," Mr. Bride continues, "Phillips would send me to the captain with little messages. They were merely telling how the 'Carpathia' was coming our way and gave her speed. Phillips told me the wireless was growing weaker.

"I went out on deck and looked around. The water was pretty close up to the boat deck. There was a great scramble aft, and how poor Phillips worked through it I don't know. He was a brave man. I learned to love him that night and I suddenly felt for him a great reverence to see him standing there sticking to his work while everybody else was raging about. I will never live to forget the work of Phillips for the last awful fifteen minutes.

"We picked up the 'Olympic' and told her we were sinking by the head and were about all down. As Phillips was sending the message I strapped his life belt to his back. I had already put on his overcoat."

Mr. Bride tells how he helped to get a life boat into the water and then walked back to Phillips and told him the last raft had gone.

"Then, came the captain's voice:" Mr. Bride goes on, " 'Men, you have done your duty. You can do no more. Abandon your cabin. Now it's every man for himself. You look out for yourselves. I release you. That's the way of it at this kind of a time. Every man for himself.' I looked out; the boat deck was awash. Phillips clung on sending and sending. He clung on for about ten minutes or maybe fifteen minutes after the captain had released him. The water was then coming into our cabin."

Phillips soon ran aft and that was the last Mr. Bride saw of him alive.

Mr. Bride describes how he was washed off the steamer as she sank and how he afterward found himself on a life raft. Some one sat on his legs but he did not have the heart to ask the man to move.

"I didn't care what happened," he continued. "I just lay and gasped when I could. At last the 'Carpathia' was alongside and the people were being taken up a rope ladder. Our boat drew near and one by one the men were taken off of it. One man was dead, I passed him and went up the ladder, although my feet pained terribly. The dead

Digitized by Google

man was Phillips. He had died on the raft from exposure and cold.

"I was then hustled down below to the hospital. That was early in the day I guess. I lay in the hospital until near night and they told me the 'Carpathia's' wireless man was getting 'queer' and would I help.

"After that I never was out of the wireless room, I just worked wireless. The splutter never died down."

Mr. Bride again referred to the incompetence of the operator on the scout "Chester." "If he had been a decent operator," Mr. Bride says, "I could have worked with him longer, but he got terribly on my nerves with his insufferable incompetence."

The "Titanic's" band was on the after deck playing "Autumn" as the ship disappeared beneath the waves. "That," says Mr. Bride in concluding his narrative, "and the way Phillips kept sending after the captain told him his life was his own, and to look out for himself, are two things that stand out in my mind over all the rest."

Mr. H. T. Cottam, the Marconi operator on the rescuing steamer "Carpathia," told an interesting story of the part he took in the wireless correspondence between the "Titanic" and other steamers concerned in the tragedy. "I got the 'Titanic's' C. Q. D.' call at 11:20 o'clock Sunday night," he said. "It was, 'come at once, we've struck a berg. It's a C. Q. D. call, old man.'"

The captain of the "Carpathia" was informed of the "Titanic's" plight and he turned his steamer at once in the direction of the "Titanic," which was then 58 miles distant.

"It was only a streak of luck," Mr. Cottam said, "that I got the message at all. I had been up until 2:30 the previous night, and the night before that until 3:00 o'clock, and I had planned to get to bed early that night."

Mr. Cottam then told how he had finished his work and made up his daily list of communications and reported them to the officer on watch. On his return he put on his telephones to exchange time with the steamer "Parisian," when he heard the "Titanic's" distress call.

The last message he received from the "Titanic" was: "Come quick. Our engine room is flooded up to the boilers."

"From 11:55 until we reached the spot where the 'Titanic' foundered," Mr. Cottam continued, "I was listening for a spark from his emergency set, but when I didn't hear anything, I was sure that he had gone down."

J. G. Phillips, the senior wireless operator on the "Titanic," who lost his life, was an Englishman, 24 years of age. He had been in the employ of the Marconi Company as an operator for about five years, and went to the new vessel from the steamship "Oceanic." Mr. Phillips's wireless service had taken him into many parts of the world. He was formerly the Marconi man on Mr. James Gordon Bennett's yacht. Entering the transatlantic service, he was assigned to the "Oceanic." Before going on the Bennett yacht, Mr. Phillips had served on a Peninsular and Oriental steamship running to the Orient. Referring to Phillips' work on the "Titanic" during the exciting moments following the fatal collision with the iceberg, the New York *Times* says, "The wireless operator seemed absolutely cool and clear-headed, his sending throughout being steady and perfectly formed, and the judgment used by him was of the best." Phillips was a native of Godalming, England, and learned telegraphy in Godalming post office. In march, 1906, he joined the Marconi School, at Liverpool, and became one of the most expert wireless operators.

Mr. Harold Bride, the second wireless operator on the ill-fated steamer, is 22 years of age, and was born at Nunhead, England. He joined the Marconi service in July, 1911, working first on the steamer "Haverford," and afterwards going to the "Lusitania," of the Cunard Line. He joined the "Titanic" at Belfast, Ireland, when she left her builders' hands, to sail from Southampton on her first trip to New York, which trip she never finished. On arriving at New York on the "Carpathia," he was carried ashore by two men on account of the injuries to his legs and feet during his trying experiences on the life raft.

Mr. Bride was a witness before the United States Senate Committee appointed to investigate the circumstances in connection with the disaster. His testimony, however, was substantially a repetition of his original story of the loss of the steamer.

Harold Thomas Cottam, the wireless operator on the "Carpathia," was born in Nottinghamshire, England, 21 years ago. At the age of 17, he learned telegraphy in Clapham, London, and received a diploma in eleven months. He has worked on several steamers and this eventful trip on the "Carpathia" was his first on that boat.

Mr. Andrew Carnegie contributed $5,000 toward the fund for the relief of needy survivors of the "Titanic" catastrophe.

Col. John Jacob Astor who was lost in the "Titanic" disaster was a member of the board of directors of the Western Union Telegraph Company.

C. M. Hays, another victim, was president of the Grand Trunk Railway, Montreal, Can., and was well-known to many members of the Old-Time Telegraphers' Association. Mr. Hays was always liberal in providing transportation over his system for the old-timers before the law prohibiting free railroad transportation went into effect.

Mr. A. C. Cronkhite, district commercial superintendent of the Western Union Telegraph Company, Indianapolis, Ind., writes: "I am indeed glad to know that you renewed my subscription in advance of advice from me. It would be a great disappointment to miss an issue of your valuable paper, which publication I can heartily recommend to those who are engaged in the telegraph and telephone business."

Many subscribers find some one special article in TELEGRAPH AND TELEPHONE AGE alone worth more to them than the subscription price of the paper which is $2 per year.

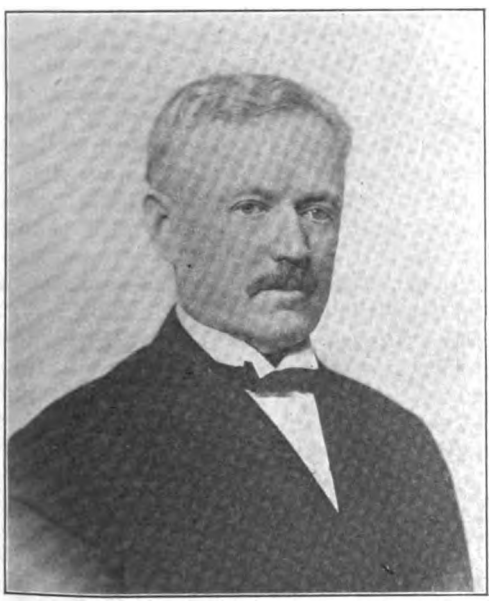
Telephone Pioneers of America.

W. T. GENTRY.

Mr. William Thomas Gentry, president of the Southern Bell Telephone and Telegraph Company and the Cumberland Telephone and Telegraph Company, with headquarters at Atlanta, Ga., is one of the leading telephone men of the day and is the head of one of the most important groups of subsidiary telephone companies of the American Telephone and Telegraph Company.

Mr. Gentry is a native of the Dominion State, having been born in Gordonsville, Va., April 14, 1854. At the age of sixteen, he entered the telegraph service as operator for the Southern and Atlantic Telegraph Company at Charlottesville, Va. He was afterwards employed at Lynchburg, Richmond and Gordonsville, becoming, in 1873, circuit manager of all the lines of the Southern and Atlantic Telegraph Company in the state of



W. T. GENTRY.
President Southern Bell Telephone and Telegraph Company, Atlanta, Ga. (1879)

Virginia. When this company was purchased by the Western Union Telegraph Company in 1876 Mr. Gentry was transferred to Lynchburg, Va., as operator for the latter company. Later he went to Wilmington, N. C., where he remained for four years, part of the time occupying the position of chief operator.

In 1879 he was transferred to the telephone department of the Western Union Telegraph Company and constructed and operated an exchange for that company in Wilmington. In 1880 he became manager of the Western Union office in Alexandria, Va., and soon after constructed a telephone exchange in that city for the Southern Bell Telephone and Telegraph Company, of which he was appointed manager. He occupied both of these positions until February, 1884, when he was appointed manager of the telephone exchange in Atlanta, Ga. In 1890 he was appointed assistant superintendent of the Georgia division of the same company in addition to his duties as manager of the Atlanta exchange. During 1893 and 1894 he had charge of practically all of the new construction work of the Southern Bell Company in the states of Georgia, Alabama, South Carolina and Florida. When the construction department of the company was organized in 1895, Mr. Gentry became general superintendent of construction and in 1899 he was appointed division superintendent with headquarters in Atlanta.

On the resignation of Mr. Chas. H. Wilson, general manager of the Southern Bell Company, in 1901, Mr. Gentry was elected to the position and in 1903 he was chosen vice-president of the company in addition to his duties as general manager.

The growth of the business was so rapid that in 1906 it became necessary to separate these two offices and Mr. Gentry relinquished the position of general manager, continuing as vice-president, however. In 1909 he was elected president of the Southern Bell Telephone and Telegraph Company which position he still holds. Under his guidance and management the business of the company has grown to very large proportions.

On February 1, 1912, Mr. Gentry was elected president of the Cumberland Telephone and Telegraph Company, Mr. J. E. Caldwell, former president, becoming chairman of the board.

Mr. Gentry was elected vice-president of the Telephone Pioneers of America at its organization meeting in Boston, November 3, 1911, and in the absence of President Theo. N. Vail, he presided over the proceedings of the meeting.

How a Messenger Left Notice.

Parkersburg, W. Va., has a force of messenger boys who cannot be surpassed. One of them perpetrated a new one on his manager a few days ago. The boy's name is Earl ("Farmer") Hunter and he is 16 years of age. Not long ago "Farmer" was given a message to be delivered about four miles in the country.

"Did you find your man?" asked the manager upon the boy's return.

"No, sir," he replied, "but I left notice."

"Where did you leave the notice?" the boy was asked.

"Right where this picture was taken," replied "Farmer," handing over a photograph of himself to verify his statement.

"But I don't see any house in this picture," replied the manager, as he glanced admiringly at the photograph.

"Sure not," said "Farmer". "The man's dead. See his tombstone there?"

The photograph shows a bright-looking messenger in uniform standing beside his bicycle near the grave of the deceased addressee of the message.

ANSWERS TO QUESTIONS.

[In this department questions on matters of a practical character, and of general interest, will be answered. Questions intended for this department must be signed by the writer's full name—not for publication, but for identity. No attention will be paid to anonymous communications.]

(91) Q. Will you please explain the meaning of the terms "cycle" and "single phase" and "three phase," which are used in connection with alternating current work. F. E. J.

A.—In order to understand the answer to the question it will be necessary to point out the difference between a direct and an alternating current. A direct current is one whose pressure (or voltage) does not vary while contact with the source of the current is maintained—that is the current is steady and unvarying in its intensity. An alternating current is one whose pressure (or voltage) is constantly changing. For example, let us take an alternator capable of generating a current with a maximum pressure of 60 volts, with only one coil on the armature. In the revolution of the armature in the magnetic field it passes a point where no current is generated. As the armature advances from this point it begins to generate current, and as it progresses the current becomes stronger until the armature coil reaches a point one-quarter of a revolution from the starting, or zero, point, when it generates its maximum current—60 volts. Then as the armature turns another quarter of a revolution the generated current decreases in pressure until the coil reaches a point directly opposite the starting point, when the current will again have dropped to zero. Let us assume that this wave of current, from zero to 60 volts and back to zero, was positive. Now starting on the second half of the revolution the armature continues to revolve in the magnetic field, from the second zero point to a point directly opposite that where it generated 60 volts positive, and will again generate 60 volts but negative this time, and the current will decrease from this point, as before, until it reaches the original starting point. It will thus be seen that in one revolution a current is generated in the armature coil that starts from zero, grows until it reaches a potential of 60 volts positive, decreases until the positive potential falls to zero, grows again until it reaches 60 volts negative, and then decreases until the negative potential falls to zero—at the starting point. All of this explanation summed up is that one revolution of an armature coil is called a cycle, and the number of cycles of an alternator depends upon the number of armature coils and the number of field magnet poles.

The simple alternator we have described is essentially a single-phase machine, that is, it generates one alternating current per revolution. If we wind the armature with three coils and space them 120 degrees apart, that is, each to be one-third the distance around the armature, three alternating currents will be generated and we will get three like currents in one revolution of the armature. Such currents are known as "three phase" currents.

(92) Q. Can you give me some information regarding the new submarine telephone cable recently laid between England and France, such as size and weight of conductor and other constructional data? D. C. O.

A. The cable is of the continuously-loaded type. The copper conductor which weighs 300 pounds per nautical mile, consists of a central copper wire surrounded by five copper tapes and the inductance loading is obtained by surrounding the conductor with a close helically-wound layer of 0.12-in. steel wire, the whole being covered in the usual way with guttapercha to a diameter of .412 in. The attenuation constants as measured after submersion and at a frequency of 1,000 alternations per second were found to be .00996 and .00987 per loop kilometre for the two circuits respectively.

(93) Q. "Suppose we have 26 volts and 60 milliamperes of current with two 150-ohm relays on one circuit and 80 volts and 60 milliamperes of current on another with two 150-ohm relays, what would be the relative capacities of each? In one case we have 1.56 watts and in the other we have 4.80 watts which is, I believe, the working capacity of the respective currents. We are also taught that the pull on the relay is the current multiplied by the convolutions of wire around the magnets. This seems to me to be somewhat confusing." C. W. H.

A. The figures given are correct, but the use of the terms is wrong. The power of a current is measured in watts, and the term "watts" relates to electric power and not to capacity, which is something entirely different. The "pull" on the armature is proportional to the current multiplied by the turns of wire on the magnets, that is, the ampere-turns, other things being equal. For example, if one ampere flowing through one convolution around a magnet core gives a pull on the armature of 1, the same current through three coils on the same core will give a pull of 3.

Pole Treating.—The San Joaquin Light & Power Company, San Joaquin, Cal., has found that untreated western yellow pine poles showed completely rotted stubs after twenty-seven months' service on its line. Of those given a brush treatment with creosote twenty-seven per cent. showed signs of decay and of those brush-treated with carbolinium twenty-nine per cent. showed signs of decay; of those treated with crude oil forty-five per cent. showed slight signs of decay. About twenty-eight per cent. of those treated with zinc chloride showed attack by decay. About fifty per cent. of the entire number of poles tested were treated with creosote by the open tank method and these were found to be perfectly sound, showing no signs of decay whatever.

Every one connected with the telegraph and telephone services should read Telegraph and Telephone Age.

Early Days of the Telegraph.

Following is a copy of an interesting letter from the late John Thomas, of Cleveland, Ohio, an old-time telegrapher, to Mr. George C. Maynard, of Washington, D. C., ex-president of the Old Time Telegraphers' Association, on the occasion of the reunion in 1891. Mr. Thomas will be remembered by many telegraphers for his lovable character, and for the encouragement he gave them during their early struggles. He was for many years superintendent of the Cleveland & Pittsburg Railroad at Wellsville, Ohio, and later, when that road passed into the control of the Pennsylvania Railroad he removed to Cleveland, where he died some years ago. The letter follows:

"My attention was first called to the telegraph by the acquaintance of my father's family, in the old town of Poughkeepsie, N. Y., with that splendid man and genius, Prof. S. F. B. Morse, the inventor of the telegraph, whose country seat was near Poughkeepsie, and whose wife was related to our family.

"Although a mere lad, I greatly admired Prof. Morse and was deeply interested in his great invention. In 1852, when I was fourteen years of age, Mr. A. G. Davis, of Baltimore, (recently deceased), was the manager of the Poughkeepsie office. He was a warm friend of mine and allowed me to come into the office as messenger, and gave me the opportunity to learn the art of telegraphy.

"In those days all operators read by paper, and I shall never forget my surprise, when on a certain occasion Mr. Davis had left me in charge of the office for a day or two (while possibly he was out repairing lines, as was then the custom) with the provision that Mr. Porter, the House operator, (also a Morse expert,) would come over and take the press report for me each evening. Mr. Porter actually took the whole report one evening by sound, and that from a relay only. It seemed to me at that time an astounding performance. Later, when most of us had acquired the same facility, we could comprehend it better.

"In the closing days of 1852, I accepted a position as operator on the New York & Erie Railway line at $25 per month. I went to Elmira, N. Y., and waited there several days for the return of Mr. L. G. Tillotson, superintendent of telegraph, who was to assign me to duty at some point on the Western Division of the road. On Christmas eve I was at the Elmira Railroad telegraph office, when the two young gentlemen, then in charge, requested me to take their places for a while as they wished to enjoy the holiday season. I agreed to do my best and they went out. About 10 p. m. they returned in a joyful frame of mind. One of them I remember (a very handsome young man) was decorated wit a string of sausages around his neck. They seemed to think that I was doing well enough, so they again went away and I saw them no more that night.

"I was finally assigned to Great Valley station on the Cattaraugus Indian Reservation and went there at once. By consent of Mr. Charles Minot, then general superintendent of the New York & Erie Railway, all the operators on the entire line arranged for a dinner at Elmira, on New Year's day, 1853. All arrived during the preceding night. On New Year's day the operators marched, preceded by a band of music, to Brainard's Hall where a meeting was held. The chief point discoursed upon was the urgent importance of operators declining to teach any more students, as the business was thought to be overcrowded, and a resolution to that effect was adopted, although I imagine was never observed by many of the operators. The dear boys had little anticipation then of the mighty development which has since taken place. At about five o'clock we had dinner. It was a fine affair. It was at this dinner that William Donnell, a witty Irishman, passenger conductor on the Western Division, was called upon to respond to a toast, which he did in a manner that 'brought down' the house. He said: 'Boys, at the last day when the great chief operator of all shall call, may yez all be found ready at your keys with the answer, 'O. K.' The effect was electrical.

"It was at this time that I first met Mr. Minot, general superintendent of the Erie road, the man who is entitled to the credit of introducing the use of the telegraph in the movement of railway trains. He was a man of brilliant genius and ability. I remained on the New York & Erie line for more than three years, during the latter part of which I was division operator at a salary of $500 per annum, and then went with D. Wilmot Smith and M. D. Woodford to the Michigan Central Railway where the movement of trains by telegraph was introduced. I was one of the train dispatchers at Kalamazoo, Mich. While there, in 1858, the first Atlantic cable was completed, the first through message being sent August 18, 1858. All the operators and dispatchers were enthusiastic. We bought candles and illuminated the station in the evening. Then we engaged a large stage coach and the entire party was driven all over the town, in most cheerful spirits.

"A few years later came the war and I went South, first in the military telegraph service, and afterward as train dispatcher on United States military railroads, with headquarters at Alexandria, Va. I was at the war department as one of the operators on the night that the election returns were received from Ohio showing that Brough was elected governor over Vallandigham.

"The war secretary, Edwin M. Stanton, was greatly interested. At about midnight he invited a number of gentlemen, including such of the telegraphers as could leave their instruments, myself among the number, to partake of a supper in one of the rooms of his department. Besides the secretary himself, General Halleck, Major Thos. T. Eckert and a few other prominent men were present. I observed that no wine was served. Stanton was a mighty man and bore his great responsibilities grandly.

Digitized by Google

"During the closing period of the war I came to Ohio with Colonel J. H. Devereux as superintendent of telegraph and later became superintendent of the Cleveland & Pittsburgh Railroad, now leased by the Pennsylvania Company.

"In 1868 I wrote to Prof. Morse, then in Europe, seeking some information as to telegraphic matters in England and received in reply from him a beautifully written and interesting letter. Prof. Morse was at that time about seventy-seven years of age. What mental and physical vigor Morse possessed even in that advanced age! This leads me to recall the fact that Samuel Finley Breese Morse was born at Charlestown, Mass., in 1791, so that this, from the standpoint of birth, is the Morse Centennial Year. Will not this add a special charm to your meeting? And will not every old-timer recall, at this time, with affectionate veneration, the name of the great founder of his craft?"

The Washington-Boston Underground Telephone Cable.

Some interesting facts are given out regarding the underground telephone cable between Boston and Washington being laid by the American Telephone and Telegraph Company which will be ready for through service toward the end of the year.

The New York-Philadelphia section is already in use and is stated to be the longest known circuit

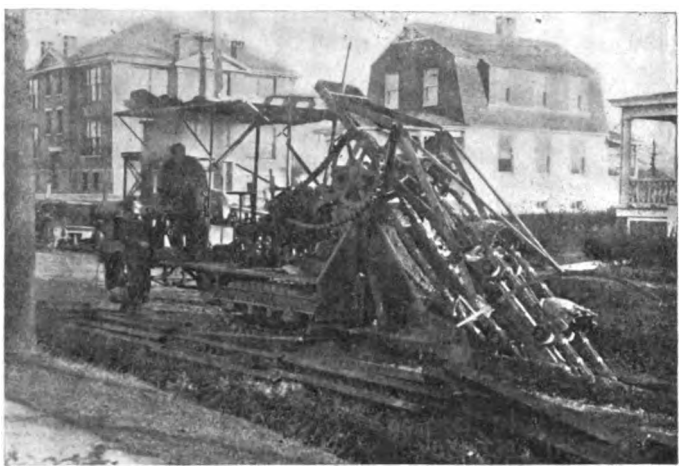

FIG. 1.—TRENCHING MACHINE AT WORK.

of its kind, and the duct work between New York and Boston and between Philadelphia and Washington is completed, and ready for the cables. These are now being laid.

The total length of line between Washington and Philadelphia is 135 miles. This necessitated the manufacture of cable weighing in all approximately 3,000 tons, requiring 1,500 reels with about 500 feet of cable per reel. The entire cable was manufactured at the Hawthorne plant of the Western Electric Company and made necessary the installation of a considerable amount of new equipment, which with the work of accumulating the raw material, consumed nearly a year before the actual work of cable manufacture could be begun. There will be in the neighborhood of 10,000 loading coils in use on the new section, and in their manufacture about 155,000 miles of iron wire are used for the cores and 7,000 miles of insulated copper for the windings.

The line in the main consisted of four ducts, made of creosoted southern yellow pine, it having been found from experience that ducts made in this way are very durable. The construction work also

FIG. 2.—TRENCH READY TO RECEIVE DUCTS.

made necessary the use of a great amount of concrete and a plant with freight facilities was established at Baltimore.

The New York-Boston section of the underground cable has not vet advanced to the same degree of completion as Philadelphia-Washington section, but its features will be practically the same and will give a continuous stretch of underground work 435 miles in length. The cable and loading coils for the entire work will be manufactured by the Western Electric Company.

The line is carried partly in trenches along the highways, and over bridges. In digging the trenches two methods were employed, by trenching machines and by trenching plows drawn by horses or mules. Fig. 1 shows a trenching machine at work, and Fig. 2, a completed trench ready to receive the ducts.

Mr. J. J. Lynch, superintendent of construction of the Postal Telegraph-Cable Company, San Francisco, Cal., writes: "I am very much interested in the articles that appear in TELEGRAPH AND TELEPHONE AGE, and assure you that I do not miss an opportunity to recommend the paper to any of our people who are not taking it, and who, I think, ought to be subscribers."

Mr. E. D. Keyes, manager of the Western Union Telegraph Company, at Hamilton, Ohio, in renewing his subscription writes: "Let TELEGRAPH AND TELEPHONE AGE come along regularly, as usual, as we cannot get along without it."

The best way to keep posted in telegraphic and telephonic progress is to read TELEGRAPH AND TELEPHONE AGE. Subscription price $2 per year.

CONSERVATION TALKS—V.

BY P. KERR HIGGINS, OKLAHOMA CITY, OKLA.

Exchange Efficiency-Grading for Vacations.

It has been customary for most companies to allow employes vacations on the basis of length of service only. There was no incentive in this practice for anyone to try to increase his efficiency and to see that others did likewise. The scheme herewith explained is, so far as the writer knows, new, and has the advantage over the old methods in that a friendly rivalry exists between exchanges, in addition to the extra vacation allowed, for meritorious service.

All employes who have been in the service of this company continuously for one year or more are entitled to a regular annual vacation of one week, with full pay.

Employes in the service for six months or more, but less than one year, are entitled to a regular vacation of one-half day for each month continuously in the service, with full pay.

For vacation allowance purposes, the year shall end May 30, and the time of service shall be counted back from that date.

The vacation due an employe shall be taken all at one time. A week of vacation shall be counted as seven consecutive days, including Sunday.

Vacations are to be taken between May 30 and September 1, unless by special arrangement with the employe's immediate superior, and vacation time shall not be cumulative—that is, an employe not taking his or her vacation this year will not be entitled to this year's time in addition to next year's vacation.

Vacations must be arranged for with the employe's immediate superior at least twenty days before the date of the commencement of the vacation, and the time selected must meet with the approval of the superior.

Employes not taking vacations will be paid a vacation bonus for all the regular and special vacation time due them, at the rate of one-half their regular salary for the time due, such payments to be made September 1. The company, however, much prefers that the employe take the needed rest. The bonus plan is to cover exceptions.

Special vacation privileges beginning..... 19... will be graded monthly as to the efficiency of the work of all departments, and each exchange will be given a grade percentage each month, which shall be made up from a summary and study of the work of each department, and the percentage so given will apply to the exchange as a whole and to all employes in all departments.

Special vacation privileges will be allowed all employes at exchanges making good ratings for the year ending June 1, 1912, as shown in the following paragraphs.

(1) At exchanges making an efficiency grade of 95 per cent. or more, all employes will be allowed one week extra vacation, in addition to the regular vacation due, with full pay.

(2) At exchanges making an efficiency grade of 90 per cent. to 95 per cent. five days extra vacation will be allowed each employe, with full pay.

(3) At exchanges making 85 per cent. to 90 per cent., three days extra vacation will be allowed all employes, with full pay.

(4) At exchanges making 80 per cent. to 85 per cent., two days extra vacation will be allowed all employes, with full pay.

(5) At exchanges making 75 per cent. to 80 per cent. one extra day of vacation will be allowed all employes, with full pay.

In fixing the efficiency rating of each exchange, the following items will be considered:

COMMERCIAL DEPARTMENT:

Percentage of collections.
Percentage of development (net increase in subscribers).
Amount of rebates.
Public relations—the company's standing with the public locally.
Co-operation and harmony with other departments.
General efficiency.

TRAFFIC DEPARTMENT:

Percentage of overtime.
Percentage of lost calls.
Complaints.
General service and efficiency; attention to operating rules; discipline.
Co-operation and harmony with other departments.

PLANT DEPARTMENT:

Promptness of installation, removals and changes.
Promptness in repairs, toll and local.
Condition of plant and equipment; cleanliness and order in operating rooms and offices.
Co-operation and harmony with other departments.
Attention to rules; general efficiency.

ACCOUNTING DEPARTMENT:

Promptness and accuracy in making reports, neatness in reports; attention to rules.
General efficiency.

The exchange vacation allowance will be based upon the average percentage of efficiency for the number of months considered. For illustration, if an exchange should have 80 per cent. one month and 90 per cent. the next month, the average percentage for the two months would be 85 per cent. The percentage for the entire period will be figured the same way.

Regular annual vacations being provided herein, the time of absence from duty for other reasons will be deducted from the employe's salary, pro-rata, excepting that one working day's absence shall not be deducted if the absent employe provides at his or her own expense or without cost to the company, for some other employe or employes to attend to his or her duties while absent, without detriment to the work. In all cases, however, such an arrangement must be satisfactory to the immediate superior or superiors of the employes concerned before it is made effective.

Other absence shall be deducted pro-rata, and the

Digitized by Google

company will settle direct with the person filling the absent employe's place.

Any exceptions to the above rules must be referred to the head of the department in which the employe works.

Duplex and Quadruplex in Railway Work.*

JOHN A. KICK.

I once heard of a railway abandoning its quadruplex system of telegraphy because it was claimed that too much trouble was experienced in maintaining the equipment and wires in full quadruplex condition.

Taking a single wire capacity as a basis, a good quadruplex circuit is equal to four wires, and where the equipment is given attention the polar side at least is better than two single wires and will give more satisfaction.

The common side of a quadruplex is what you make and maintain it; that is, if the line wire is within the limits of good quadruplexing distance, then the question is one of upkeep, and the returns in added service surely justify first-class maintenance and attendance. If the line wire is so long as to make "fair weather" service only, then the old familiar phrase "you cannot get something for nothing" applies just as it does when you attempt to maintain multiplex equipment by having inferior quality of maintenance and attendance. A quadruplex properly installed and working on a wire well within the limits does not require a great amount of attention, but what attention it does need and receive must be from a skilled attendant.

There is usually enough business between the general headquarters and each division headquarters to require the full service of one or more single wire equivalents and since the usual string of way offices cut in on these circuits are unable to secure service, they had best be cut out altogether and the wire quadruplexed or duplexed, thus multiplying the capacity by two or four.

In general it is more satisfactory to relay business for local points on any division at the main telegraph office on that division than to attempt a general direct service between all stations. For many reasons the method first mentioned is more satisfactory.

First: The through wires are decreased in resistance by the cutting out of office equipment at way offices which are rarely ever able to get the circuit long enough to raise an office.

Second: The lag introduced by a circuit overloaded with relays is cut to a minimum.

Third: The circuit is made a duplex or quadruplex possibility, increasing the capacity two or four-fold.

Fourth: If desired, the through circuit may be quadruplexed from division point to division point with the polar side cut through using the common side for business between the division points or cutting it through as required.

Fifth: There are many possibilities of half set repeatering of side line and branch circuits through over these quadruplexed circuits, and while the intial installation will appear to call for added relay service there will eventually work out possibilities of offsetting this increase by using the added facilities for carrying direct the business formerly relayed from these circuits.

Sixth: If remaining single but strictly through with no way offices, the maximum speed of operation is secured as a single wire. If duplexed and two-way service secured, a higher speed is made possible by reason of the "clearing out" feature of the operation of a pole changer as against a continued direct current applied, which is the case under single wire operation. As the higher speed is possible both ways, it is clear that one wire duplexed will carry more business than two like single wires. If the distance is within the limit of a good quadruplex, then the capacity is increased four-fold, as the latest type of quadruplex equipment is of such efficiency as to allow the very highest speed of operation.

The question of determining requiremnts properly to handle the business is one that is not easily decided, and an attempted study of the proposition will result in a lot of detail work becoming apparent and bringing to notice the fact that there is a very important traffic feature to a well organized railway telegraph system.

Telephone Engineer.

New Time Service Catalogue.

The time service department of the Western Union Telegraph Company, New York, has issued a new time service catalogue, which may be obtained in quantities desired, upon requisition on the supply department in the usual manner.

The catalogue gives illustrations of the various designs of clocks furnished on a rental basis and the rates applied to each clock under yearly contract.

Directions for regulating master clocks equipped with both wooden and mercurial pendulum are fully described with valuable information, which, if carefully observed, will very materially aid in the proper regulation of the master clocks and the rendition of service that will be satisfactory and commendable to time-service subscribers.

The catalogue shows the new signs recently adopted for display purposes on clocks, reading:

U. S. Observatory Time
Hourly by
Western Union,

instead of the abbreviation W. U. Tel. Co. as on the old signs. The new signs are much more attractive with the improved lettering and bring out the words "Western Union" much more prominently. These new signs will be ready for distribution in the near future.

Attention is called to the telegraph company's day and night letter service, cable messages and fast messenger service, and on the front and back covers the new Western Union circular sign is conspicuously displayed.

The General Railway Equipment Company.

The announcement made by the offer by the bankers for subscription to the stock of the General Railway Equipment Company marks the accomplishment of a union of the selector telephone train dispatching interests which has been under consideration for some months past. The new corporation has a capital of $15,000,000 and a board of directors of weight and influence in both the financial and the railway worlds. The board of directors comprises Messrs. Newman Erb, long identified with the Hawley roads; Jules S. Bache, of J. S. Bache & Company, bankers; the Hon. John W. Griggs, ex-attorney-general of the United States and counsel to the Marconi Company; James Gayley, chairman of the United States Steel Corporation; W. G. Besler, vice-president and general manager of the Central Railroad of New Jersey; Charles N. Sigison, treasurer of the United States Electric Company, and George M. Seeley, of the National Telephone Selector Company. The new company succeeds to the business of the United States Electric Company, the National Telephone Selector Company, the Sandwich Electric Company, the Sandwich Pole Changer Company, the Charter Electric Company, the Electric Switch and Signal Company, and the International Telegraphic Call Company.

As is indicated by the names of the constituent companies the General Railway Equipment Company comes into ownership and control of the Gill, the Sandwich, the National and the Wray-Cummings selectors, the aggregate of which in service is said to far outnumber those of all other makes combined. Beside these the new company will own and control a large number of patents, many of them basic and fundamental, covering the essential features of telephone dispatching, message and signal service as used on American railroads to-day. The company will have the services of the engineers who have developed to its present efficient stage the art of dispatching both in its selector and telephone equipment branches and will begin business with a large number of orders on its books. Beside the economies consequent on a centralized control, the new company will have at command a force of technical representatives both at its local offices and on the road, familiar with the requirements of the roads and with a wide acquaintance among railroad officials. Its ample capital is a guarantee of its financial strength and of its ability to take care promptly of contracts of any magnitude. Its standard output will cover practically the entire line of railway electrical equipment.

Wireless in Russia.—The Russian Government proposes to establish four wireless stations on the shores of the Kara and White Seas, at a cost of 100,000 roubles, to facilitate commercial intercourse between Siberia and Europe by way of the Arctic Sea.

Telephone Pioneers of America.

The proceedings of the first annual convention of the Telephone Pioneers of America, which was held at Boston, Mass., November 3 and 4, 1911, have been published in book form and copies are now being distributed to the members. Every detail of this interesting meeting is recorded and the results of the work reflect great credit upon secretary Henry W. Pope. He has displayed much artistic and editorial talent in the make-up of the book, and the members will feel highly pleased with his achievement.

The cover is in telephone blue, the lettering and designs being neatly embossed in gold, a representation of Bell's first telephone being shown on the back cover.

The book has several excellent illustrations including portraits of those gentlemen most prominently identified with the organization. Full page portraits of Dr. Alexander Graham Bell and Mr. Theo. N. Vail are beautifully printed in Sepia on artist paper of a light brown tint, and lists of the members, arranged alphabetically and geographically, are given at the back of the book.

Philadelphia Postal News.

Among the recent visitors at this office were D. H. Gage, Jr., and G. D. Wilkinson, of New York, H. L. Krum, of the Morkrum printer, New York, and M. Ruberg of the American Telephone and Telegraph Company, Philadelphia.

J. M. Elder is in Baltimore on business.

Police Telephones.—The Berlin police are all provided with pocket telephones, and connection boxes are fixed in every street, so that communication can be immediately effected with headquarters. The pocket apparatus fits into a nickel case two and one-half inches in diameter by three-quarters of an inch thick, and weighs only seven ounces.

Death of Mr. Boone.

L. N. Boone, aged 54 years, for thirty-five years an operator for the Western Union Telegraph Company at St. Louis, Mo., died in that city April 18. He was at one time chief operator in the St. Louis office, and was retired on a pension some months ago.

New Fire Alarm System for Sacramento.—The city of Sacramento, Cal., will install the Gamewell fire alarm telegraph system.

Valuable Electrical Book.

Vest Pocket Electrical Dictionary. A practical hand book of reference containing definitions of electrical terms and phrases in use in every branch of electrical science. It is especially valuable to telegraphers and telephonists, and will be found a great aid in understanding electrical apparatus and applications of electricity in general. Price 50 cents per copy. For sale by TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Arrangements for Convention of Railway Telegraph Superintendents.

A meeting of the entertainment committee of the Association of Railway Telegraph Superintendents was held April 16, in the office of Mr. L. S. Wells, superintendent of telegraph, Long Island Railroad, New York.

It was finally decided to make the Waldorf the association's headquarters, and to hold the meetings at the same place, instead of in the United Engineering Societies Building, as originally proposed.

The rates for accommodations at the Waldorf-Astoria are as follows:

Two dollars per day for single room without bath for one person, with bath, $3.00 up.

Double rooms for two persons, without bath, $4.00 per day up, with bath, $5.00 up.

Two double rooms, with bath, for four persons, from $8.00 up, for the two rooms, or $4.00 per room.

The tentative programme, as published in our issue for April 16, was slightly changed in a few details.

On Monday, June 3, an informal reception will be held at the Waldorf at 8:30 p. m.

On Tuesday, June 4, there will be business meetings morning and afternoon, and the ladies will be taken on a sight-seeing tour in automobiles in the afternoon. At night there will be a theatre party, as already announced.

The programme for Wednesday is unchanged. There will be a shopping tour for the ladies in the morning and in the afternoon the men will make a visit of inspection to the Western Union Telegraph Company's headquarters, and the New York Telephone Company's Cortlandt Street Exchange, and at 5 p. m. the entire party will take a trip to Coney Island by steamboat.

On Thursday there will be business sessions morning and afternoon and the ladies will be taken on a trip around Manhattan Island by boat. In the evening the entire party will attend a roof-garden entertainment.

On Friday a visit will be made to the Edison works, at West Orange, N. J., and after luncheon at the Country Club at West Orange, as the guests of Mr. Edison, the party will return to New York over the Erie Railroad and land at West Twenty-third Street, where they will take automobiles for the Country Club, Travers Island. At Travers Island, the party will be entertained at a clam-bake given by Mr. Belvidere Brooks, in behalf of the Western Union Telegraph Company.

It was the sense of the meeting that buttons be supplied to the members instead of badges, and a sample button submitted by Mr. W. E. Harkness met with general approval.

The advisability of having an exhibition of apparatus and appliances was discussed, the general sentiment being against it on account of lack of time out of business hours and entertainment to give the exhibits the proper inspection. The matter, however, was referred to Mr. A. P. Eckert to ascertain the views of the various companies that usually have exhibits at these conventions.

The following members of the committee were present: L. B. Foley, E. P. Griffith, L. S. Wells, A. D. Walters, and E. E. Hudson. Messrs. A. P. Eckert and W. E. Harkness were also present.

The Turner Monument Dedication.

All arrangements have been completed for the dedication on May 2 of the monument at Harriman (formerly Turner), N. Y., to commemorate the sending of the first telegraphic train order, and there is every indication that there will be a large attendance.

Mr. E. P. Griffith, chairman of the monument committee, has arranged for the presence of 200 school children, who will sing in the exercises. The children will be given a holiday for the day, and this feature of the programme will no doubt be highly appreciated by all present.

The programme of the exercises was given in our issue for April 16 and it will be adhered to as there announced.

A special train will leave the Erie station, Jersey City, N. J., at 10:20 a. m., May 2. It will consist of two Erie Railroad private cars, the Western Union Telegraph Company's private car, one first-class coach, and one combination coach. The train will remain at Harriman until the close of the ceremonies, and will return at once thereafter, reaching Jersey City about 2 p. m.

All railroad, telegraph or telephone employees and dependent members of their families are entitled to free transportation and can procure the same by making application through the regular channels.

Round trip tickets New York to Harriman can be purchased at any Erie Railroad ticket office for $1.95 each.

Meeting of Telegraph Superintendents of New York Central Lines.—The regular quarterly meeting of the superintendents of telegraph of the New York Central Lines was held at Cleveland, Ohio, April 18, to consider general matters pertaining to the service Those present at the meeting were: W. W. Ryder, general superintendent, Chicago, Ill.; and the following superintendents: E. C. Keenan, Lake Shore & Michigan Southern, Cleveland, Ohio; A. B. Taylor, New York Central & Hudson River Railroad, New York; J. J. Ross, Michigan Central, Detroit, Mich.; C. S. Rhoads, Cleveland, Cincinnati, Chicago, & St. Louis, Indianapolis, Ind.; G. C. Todd, Nickel Plate, Cleveland, Ohio, and W. L. Connelly, Chicago & Indiana Southern, Gibson, Ind.

Mr. T. C. Harlan, of the Western Union Telegraph Company at Kankakee, Ill., in renewing his subscription for another year, writes: "To be without TELEGRAPH AND TELEPHONE AGE would make me feel that I were isolated from the world in which I am naturally most interested."

Dinner of Magnetic Club.

The spring dinner of the Magnetic Club, New York, was held at Mouquin's on Fulton Street, April 24 and was attended by a large number of members and guests.

The meeting at a down-town establishment was an innovation, and although the quarters were somewhat limited, there was no lack in enthusiasm and good-fellowship.

All present sat down to the tables at 7 o'clock and enjoyed an excellent dinner, served in the style for which Mouquin's is famous. Music from a fine orchestra, and singing, enlivened the occasion and put every one in a happy frame of mind.

At the conclusion of the dinner president C. P. Bruch introduced the principal guest of the evening, Hon. W. A. Prendergast, controller of the City of New York, who made an address that was frequently punctuated by hearty applause.

The keynote of Mr. Prendergasts' speech was efficiency in public service. He paid a graceful compliment to the Postal Telegraph-Cable Company on its progressiveness and its policy of rendering quick service to the public. Too many persons and corporations, he said, tended to follow the line of least resistance and such methods would never result in progress. Mr. Prendergast then cited several instances where he had applied scientific management in city departments and mentioned the opposition he had encountered from men who were slaves of the old regime. A point which we must not neglect, he said, however, is the possibility of losing sight of the personal element. The maximum amount of work must not be placed above the development of the proficient qualities of the man himself. We should strive to broaden and develop him. The first duty of society is to man and our laws should safeguard him from early childhood both as regards conditions of employment and discrimination against any class. This conservation of our flesh and blood, Mr. Prendergast said in conclusion, is the ideal Americanism.

Mr. Bruch then introduced Mr. D. D. Moore of the New Orleans *Times-Democrat*. Mr. Moore described himself as being not a telegraph man, but an "ultimate consumer." He touched upon the close relations between the newspapers and the telegraph and humorously denied the aspersions which the telegraph had cast upon his State, Louisiana, in representing that a large part of her was submerged by the recent floods. They still had a few acres above water, he said, and were constantly reclaiming new areas.

As chairman of the James Douglas Reid Memorial Committee, Mr. Bruch reported that a pamphlet, setting forth the plans of the committee, had been prepared and would shortly be sent out.

Mr. Armour was then introduced, who kept the company in a continuous roar of laughter with his cleverly rendered songs and stories.

After a short intermission the special entertainment features were presented. The artists rendered an excellent performance and received many encores. The dinners of the Magnetic Club are always most enjoyable and the present one was no exception.

Those present were:

Complete Visible Writing

This is the great distinctive feature of the MODEL 10

Smith Premier Typewriter

Complete Visible Writing means not only that the writing itself is visible, but that the operating machinery which produces the writing is also visible. Above all it means that the keyboard is completely visible.

Why? Because it is the only typewriter having a key for every character—hence the character printed by each key is always the same. This distinctive feature has won for the Smith Premier Typewriter an immense army of loyal users.

EDISON BSCO PRIMARY BATTERY

THE importance of maintaining service of such a grade, in telephone train despatching, that words are not liable to be confused, is fully recognized by telephone superintendents and engineers.

This universal feeling has resulted in the development of a very fine line of instruments, and the installation of expensive lines. With these branches of the system satisfactorily taken care of, it is important that the battery used meets the particular requirements of the transmitter circuit, otherwise much of the carefully designed and constructed system goes for naught.

All students of the art understand that the inventions of recent years which improve the efficiency of the transmission are based on the theory that all waves must be of equal velocity, and it must be apparent to all that a battery of the open circuit types, which cannot maintain its voltage under constant discharge will not cause a transmitter to send out uniform impulses.

The Edison BSCO cell is ideal for the service because it maintains a uniform voltage, and in adopting this cell for your talking circuits, you not only improve the service but effect an economy.

Catalog and Particulars on Request.

Wired-Wireless Telegraphy.

The April number of the *Journal of the Franklin Institute,* Philadelphia, Pa., contains an article by Major George O. Squier of the Signal Corps, U. S. A., describing some preliminary experiments in "wired-wireless" telegraphy. The article is illustrated and the author summarizes the results of his experiments as follows:

"This brief paper has outlined some methods of telegraphy involving the principles of the wireless art as applied to wires. It has been shown that the wireless telegraph equipment developed by the Signal Corps for use on aeroplanes or for communicating with mobile troops in the field, can be employed to create additional telegraphic channels of communication as follows:

"(*a*) The standard insulated field wire furnished to the Signal Corps, when paid out on the ground and normally operated by the standard field buzzer, may be efficiently used to transmit Morse signals by electric waves by connecting it directly or inductively to the 500-cycle generator supplied for the wireless equipment, and the signals interpreted at the receiving end of the line by the standard low-resistance telephone.

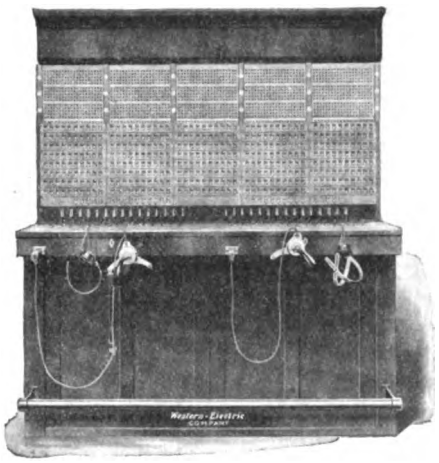
"(*b*) This same wire may also be used to guide the high-frequency electric waves transmitted by the complete field wireless quenched spark sending set and received by the complete wireless receiving set with the usual detector and high-resistance telephones. This gives three well-defined and distinctly separated methods of transmitting intelligence over wires, and permits the possibility of using them either separately or in any operative combination in accordance with the particular requirements of the case. These results can be accomplished without the addition of a single piece of apparatus over what is already in the hands of the field companies of the Signal Corps."

New Magneto Multiple Switchboard.

The Western Electric Company has developed a magneto multiple switchboard with a jack for every line within easy reach of each operator. It is known as the No. 1013 type, and is designed for use on local battery magneto telephone systems where, on account of local conditions, a central battery board would be out of the question.

This switchboard is intended for telephone systems having an ultimate capacity of 1,500 lines or less where the traffic conditions make it necessary to take advantage of the inherent rapidity and efficiency of operation obtained with a multiple switchboard. The sections are five-panel, two-position and, when lined up in the operating room, present the appearance of one continuous cabinet. A cable turning section with a terminal rack is provided for the head end of the switchboard line-up, matching the other sections in design and finish.

The line and cord circuit apparatus makes use of the combined jack and signal with the red spherical shutter. The multiple jacks are mounted in strips of twenty, each jack being on an individual frame so that any one may be removed at will. The clearing-out signal or supervisory sig-



MAGNETO MULTIPLE SWITCHBOARD

nals are modified combined jacks and signals in which the jacks have been replaced by push buttons for restoring the signals. This provides positive supervision.

Portable Sound-Proof Telephone Booths.

After considerable experimental and research work, a practical sound-proof booth for telephone service has been developed by the Western Electric Company. The booths have double, interchangeable walls, with an air space between, which excludes outside noises and secures privacy. They are mounted on rubber cushions. The doors can be furnished in either the single or double pattern to swing to the right or left, as desired. Wooden panels are interchangeable with glass sashes, which are removable to facilitate cleaning. Compartment booths can be supplied in any number desired. Bulletin No. 1083, issued by the Western Electric Company, gives a detailed description of these booths.

Telegraph Typewriter Patent.—Mr. Donald Murray, of London, England, the well-known inventor of the printing telegraph system bearing his name, was on April 2 granted a United States patent (No. 1,021,942) on a "printer for multiplex printing telegraph systems." The invention consists of power-driven selecting and printing mechanism for operating a typewriter.

Artillery Review.—Grand-Regent R. H. Starrett and staff of the Royal Arcanum, reviewed the Thirteenth Regiment Coast Artillery in Brooklyn, N. Y., April 8. Mr. P. J. Tierney, of the central cable office of the Western Union Telegraph Company, New York, was one of the reviewing officers as one of Mr. Starrett's staff. The exercises were very interesting and there was a crowd of 9,000 present.

Western Electric Business.—Decreases which marked the first two months of the Western Elec-

Digitized by Google

tric's current year came to a halt in March, when sales ran about equal with March, 1911. The first quarter of 1912 shows sales at the rate of about $67,000,000 for the year, or slightly better than 1911, which showed sales of $66,200,000.

"Dots and Dashes" at Dinner.—The "Dot and Dash" Club of Philadelphia, which, as already announced, will hold its first dinner, May 11, and has invited as guests several well-known and prominent telegraph people, including Messrs. James Merrihew, David Homer Bates, and Charles P. Bruch, of New York. Ex-governor Stuart, of Pennsylvania, has also been invited to attend the dinner.

Philadelphia Electrical Aid Society.

The Electrical Aid Society of Philadelphia held a very successful entertainment Friday night, April 19. Several hundred persons attended the entertainment, supper and dance, and the proceeds collected were large.

The vaudeville entertainment started at eight o'clock and the dancing continued until midnight. William R. Harmstad is president of the society. The other officers are: vice-president, A. G. Strickland; recording secretary, W. E. Vanarsdall; financial secretary, R. C. Murray, and treasurer, James H. Wilson.

Western Union News from Denver.

Mr. W. McD. Milne, division auditor, Denver, Col., has been transferred to Chicago, as acting division auditor. He is being succeeded by Mr. C. W. Carver of New York.

Miss Pearl M. Cairns, of New York, has been appointed manager at Santa Fe., N. M., vice A. B. Bush, resigned.

Mr. R. W. Gray, division plant superintendent, San Francisco, Cal., was a recent visitor at Denver. Mr. W. Salisbury, district plant superintendent, Omaha, Neb., recently visited Denver on company business. Mr. P. L. Mounce, manager, Indianapolis, Ind., was a recent visitor at Denver.

Mr. B. L. Brooks, division traffic superintendent, and Mr. E. E. McClintock, district commercial superintendent, Denver, have returned after an inspection trip to various New Mexico points.

General superintendent J. C. Nelson has returned after an extended trip over his division.

Mr. C. R. Fisher, district plant superintendent, Denver, has completely recovered from his recent operation for appendicitis, and has resumed his duties.

An independent office has been opened at La Junta, Col., Mrs. A. R. Woods, formerly manager at Telluride, Col., being appointed manager. Mrs. Woods was succeeded by Mr. Frank Shadell, formerly manager at Cripple Creek, Col., and Sheridan, Wyo.

Mr. E. A. Thompson, manager, at Paonia, Col., has resigned to go into the publishing business, having bought the local newspaper at Paonia. He is succeeded by Mr. H. Redfield, formerly night operator at Cripple Creek, Col.

New York Western Union Notes.

Mr. Robt. H. Morris, electrical engineer of the operating department, has the sympathy of many friends in the loss of his wife, who died at Roselle, N. J., April 13 at the age of 66 years. The remains were buried at Glendale, N. J. Old-timers will remember Mrs. Morris as the happy good-natured operator at old "DX" office, 134 Pearl Street, New York, which was under the management of Mrs. M. E. Lewis. Mrs. Morris is survived by her husband and two children, George W. and Maud A.

Among sound and reliable insurance organization the Telegraphers' Mutual Benefit Association of 195 Broadway, New York, occupies a foremost place. Organized in 1867, it has paid to beneficiaries of deceased members $1,650,000. Reserve Fund, $328,000, the largest Reserve in proportion to liabilities that is held by any similar association. All persons engaged in telegraph or telephone service between the ages of 18 and 45 are eligible for membership, no restrictions after admission as to change of occupation or residence. The lowest possible cost consistent with security offered. Write for blanks and further information.

WHEN YOU STOP TO FIGURE the cost per issue, only 8 1/3c., as compared with the wealth of material in each issue, you will join the army of "100% value" subscribers—I mean those that get each issue of TELEGRAPH AND TELEPHONE AGE at home—at home, so that the full benefit is received of each number.

Two dollars takes care of the next twenty-four issues—let me send them home for you.

Order today from E. Schwartz, All Magazine Subscriptions, 53 Avenue D, New York, N. Y.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

Progressive Methods—The Unit System.

When one compares the equipment of a modern telegraph office with that of one of not many years ago he is impressed with its altered appearance, but seldom does one really appreciate the real factors which have made such changes possible.

The usual conclusion arrived at by many is that the business, filling a long-felt want, grew of its own accord so rapidly that the company was able to enlarge and elaborate its plant by the mere expenditure of the money thus received, granting, of course, good management.

Good management is the principal factor in every industry, but let us see what auxiliary methods the managers have evolved that have contributed much toward the present high state of efficiency.

During the early period of telegraphy progress consisted principally in the enlargement of the plant, developing new and improved apparatus, and educating the people to appreciate the advantages of quick communication. There was little or no profit in the industry at first; every new venture was guesswork and a hazard. There was no uniformity in construction, and each office was adjusted to the conditions then prevailing. Being an adjunct in a railroad station or a drug store, the office was installed to suit the environments.

Naturally the equipment was not interchangeable between offices, and economy derived by uniform construction was probably never thought of, but today uniformity is the principal factor in the economical and rapid development of the telegraph. Today each piece of apparatus or equipment is, or soon will be, a unit, interchangeable with any other similar part, in any office and at any time.

Not only that, but each unit is given a type number together with a description of its particular construction, use and operation. This information is printed and distributed to all employes directly concerned.

Tables for multiplex and repeater apparatus are constructed of uniform dimensions and spaced for a uniform layout and assembly for each class. Unnecessary and inefficient equipment has been discarded; such, for example, as that of the terminal switchboard in the cellar for incoming wires. Today one distributing frame near the operating switchboard fills the requirement in a more satisfactory manner and at the same time saves not only space, but considerable expense in work, wire and other material.

The mounting for each class of units is itself also a unit, constructed to take care of a given number of other apparatus units within a specified space on the table or elsewhere.

What is particularly noticeable is the smaller dimensions of recent apparatus and other items of equipment. For example, the condensers are very small as a rule compared with the older designs. The old type 3 M. F. condensers used on multiplex circuits occupied a box about 18x24 inches in size and weighed several pounds. Today we can get its equivalent in the hip pocket and experience little discomfort from its weight. A dozen of them may be readily concealed under the table framework, if necessary, and the space formerly occupied by condensers can be utilized for other purposes. In actual practice part of this space is now taken up by a combination condenser box unit much smaller than the former type, yet containing a number of other condensers required in the operation of quadruplex circuits.

Another innovation in telegraph engineering is that of using enameled wire in place of inflammable silk or cotton-covered wire in the windings of sounders, relays and other magnet coils. This wire has been found not only more durable, but it occupied less space. Silk and cotton covering becomes carbonized when overheated by excessive currents; and as carbon is a good conductor of electricity, the current in time cuts across adja-

Digitized by Google

cent convolutions and thus creates a "lopsided" relay in the differential types, or a defective one in the single line apparatus.

Last but not least uniformity in apparatus, installation, and instructions concerning the operation tends toward better results all around. Each attendant, regardless of where he works, receives the same official instructions and becomes familiar with the assembly and operation of apparatus in vogue, no matter what office he may be working in. He himself is therefore instantly "interchangeable" as a substitute, or available in cases of emergency, wherever required.

Historians have divided the past into epochs designated the Stone Age, the Iron Age, etc.; but surely there is no term that would so fittingly represent the present, as "The Unit Age." (Future historians please note.)

1,023,482. Party-Line Selective Signaling System. To C. E. Scribner, Chicago, Ill.

1,023,557. Multiple Telephone-Transmitter. To C. E. Egner, Stockholm, and J. G. Holstrom, Saltsjo-Storangen, Sweden.

ISSUED APRIL 23.

1,023,900. Telephone System. To H. G. Webster, Chicago, Ill.

1,024,088. Signal-Transmitter for Telephone Exchanges. To G. W. Lorimer, New York.

1,024,131. Detector for Party-Line Telephones. To H. Y. Haley, Rushsylvania, Ohio.

1,024,184. Automatic Telephone-Exchange System. To G. Deakin, Berkeley, Cal.

1,024,205. Printing Telegraphy. To Isidor Kitsee, Philadelphia, Pa.

1,024,444. Automatic Signal-Operator. To E. R. Gill, New York.

1,024,445. Selective Signalling System. To E. R. Gill, New York.

1,024,446. Signaling System. To E. R. Gill, New York.

1,024,487. Telephone-Exchange System. To E. E. Clement, Washington, D. C.

ISSUED APRIL 30.

1,024,498. Telephone System. To H. P. Clausen, Chicago, Ill.

Telegraph and Telephone Stock Quotations.

Following are the closing quotations of telegraph and telephone stocks on the New York Stock Exchange May 11:

American Telephone and Telegraph Co....146
Mackay Companies 82
Mackay Companies, preferred..... 68⅝
Western Union Telegraph Co..... 84

Personal.

Mr. D. H. Bates, Jr., son of Mr. David Homer Bates, secretary of the Society of the United States Military Telegraph Corps, New York, was married on May 15 to Mrs. Eleanor Loring Lord.

Mr. Cecil P. Poole, a former telegrapher, and for the past seven years co-editor of *Power*, New York, has retired from editorial work to engage in engineering practice in Atlanta, Ga.

Mr. F. Douglas Watson, general manager and secretary of the Constantinople Telephone Company, has returned to Constantinople after spending two or three weeks in England.

Mr. F. J. Scherrer, secretary to Col. R. C. Clowry, formerly president of the Western Union Telegraph Company, New York, has returned from Chicago and Omaha, where he went on business.

Mr. W. H. Sawyer, a well-known old timer, and for many years actively identified with the Phillips Insulated Wire and Cable Company, Providence, R. I., has returned to his Providence home from Pasadena, Cal., where he spent the winter.

Mr. Jeff W. Hayes, of Portland, Ore., a well-known old time telegrapher and author, is now a special correspondent for *The Oregonian*, of Portland. Mr. Hayes expects to visit the larger cities throughout the United States and Canada for his paper.

Mr. Francis W. Jones, former electrical engineer of the Postal Telegraph-Cable Company, New York, accompanied by Mrs. Jones, has returned from Palm Beach, Fla., where they spent the winter. They will take up their residence at Spring Valley, N. Y.

Mr. J. E. Peacock, former manager of the Jacksonville, Fla., Western Union office, was, on April 30 nominated in the Democratic primary election for treasurer of Duval County, Fla. The nomination is equivalent to election. Mr. Peacock, since leaving the Western Union service in January, 1911, has been successfully engaged in the real estate business in Jacksonville. He will continue in the real estate field after assuming the duties of county treasurer.

Mr. Guy E. Paine, formerly superintendent of the Postal Telegraph-Cable Company at Chicago, Ill., has become a member of one of the most successful insurance firms in the South, which is located at Atlanta, Ga. The style of the new firm is Bagley, Willett & Paine. Mr. Paine will have charge of the independent agency at Macon, Ga., and his territory will cover over thirty counties in central and southern Georgia. He has had a wide business experience and is eminently fitted for his new line of work. Mr. Paine will give his entire time to the business of the new agency, and his many friends in and out of the telegraph service wish him much success in his new field of endeavor.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. E. J. Nally, vice-president and general manager, New York, is in New Orleans, La., at the present time and expects to return to New York in a week.

Mr. Edward Reynolds, auditor, has been appointed fifth vice-president of this company, in recognition of services.

Mr. Minor M. Davis, electrical engineer and chief engineer of telephones, New York, has been in Chicago on company business for the past two weeks.

Mr. Edward S. Williams, manager of the Chicago office, has been appointed superintendent of the first district, western division, to succeed Mr. H. G. McGill, who becomes superintendent of the second district.

Mr. John Nering, for many years assistant manager of the Chicago office, has been appointed manager to succeed Mr. E. S. Williams, promoted. The position of assistant manager has been abolished for the time being.

Manager J. A. McNichol and cashier J. H. Wilson, of the Philadelphia office, visited New York recently to study the organization and operation of the Mutual Investment Association with a view to starting a similar organization in Philadelphia. Such associations are now in successful operation in Chicago and Washington as well as in New York.

During the absence of chief operator A. Klein, at Birmingham, Ala., who left May 9, for Hammond, La., to take a much needed rest, traffic chief E. E. Hydinger will act as chief operator; night chief operator R. D. Burger will act as traffic chief; all-night chief operator R. L. Figgatt, as night chief operator; night traffic chief C. J. Raley, as all-night chief operator, and operator J. A. Price, as night traffic chief. Mr. Klein, who is one of the most efficient chief operators in the South, will probably be absent three months.

Edward Reynolds, Fifth Vice-President, Postal Telegraph-Cable Company, New York.

Mr. Edward Reynolds, whose election as fifth vice-president of the Postal Telegraph-Cable Company is announced in the executive column, received this appointment as a recognition of his faithful services. He still retains the active position of auditor of the company n New York, of which he is also a director.

Mr. Reynolds was born at Catskill, N. Y., November 11, 1866, and began his telegraphic career at the age of 18. Coming to New York in 1889, his service with the Postal Company began on August 1 of that year as an operator. His faithfulness, intelligence and capacity met with early acknowledgment, and on April 1, 1891, he became chief clerk to superintendent E. G. Cochrane. On February 1, 1897, he was appointed to a like position in the office of the general superintendent, thence on July 1 was promoted to the chief clerkship in the office of vice-president Bradley. On January 1, 1900, he was advanced to the position of assistant auditor, and on May 1 of the same year to that of auditor, which position he still holds with credit to himself and satisfaction to his company.

EDWARD REYNOLDS,
Fifth Vice-President and Auditor, Postal Telegraph-Cable Company, New York.

Telegraph Money Order Forger Convicted.—George P. Westerfield, operator at Hot Springs, Ark., forged two telegraphic messages on the morning of April 9, dating them New Orleans, La., and addressed to the Arkansas National Bank, Hot Springs, Ark., instructing it to pay him nine hundred dollars. The bank suspected fraud, refused payment, and on investigation Westerfield was arrested. Almost immediately after his arrest, he was indicted by the grand jury. Westerfield was tried on April 29, convicted on the charge of forgery, and sentenced to four and one-half years in the penitentiary.

To Entertain German Naval Officers.—Messrs. Clarence H. Mackay, president Postal Telegraph-Cable Company; W. C. Brown, president New York Central Lines; Melville E. Stone, general manager Associated Press, and Andrew Carnegie, are among the members of the reception committee appointed by Mayor Gaynor of New York to entertain the officers and crew of the German warships, which are due at New York June 9.

Mr. H. W. Carty, local manager of the Diamond State Telephone Company, Salisbury, Md., writes: "I have just finished reading the May 1 issue of TELEGRAPH AND TELEPHONE AGE and I wish to assure you that it is one of the most instructive journals that I have ever had the pleasure of reading."

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr. Theo. N. Vail, president of the American Telephone and Telegraph Company and of the Western Union Telegraph Company, who has been in Europe for several weeks, is expected back in New York toward the middle of June.

Mr. Newcomb Carlton, vice-president of the company, who has been on a business trip to Chicago, Omaha, Denver and Pacific Coast points, accompanied by his secretary Mr. E. Everett, is expected back at his office the first of next week.

Mr. Belvidere Brooks, general manager; Mr. A. G. Saylor, general superintendent, and Mr. E. M. Mulford, division commercial superintendent, of this company, all of New York, were in Boston last week on business connected with the service.

Mr. L. A. Harrison, of the Albuquerque, N. M., Santa Fe office, has been attached to the plant department of this company, with headquarters at Denver, Col. Much sympathy is expressed for Mr. Harrison in the death of his wife, which occurred on April 13.

Mr. W. E. Dickinson, manager of the Worcester, Mass., office has been promoted to a position in the office of Mr. E. M. Mulford, division commercial superintendent, New York.

Mr. R. L. Jackson, formerly manager of the Western Union Telegraph office at Atchison, Kan., is now manager for the same company at Victoria, B. C.

Mr. T. A. Darling, manager of the Postal Telegraph-Cable Company of Texas, at Beaumont, Tex., has resigned to accept the managership of the Fort Worth, Tex., office of this company.

Mr. C. H. Frary, of Lawrence, Kan., has been appointed assistant to manager E. J. Sullivan of the Wichita, Kan., office.

The Spring dinner of the Commercial Managers' Association of New York was held at the Broadway Central Hotel May 4. Addresses were made by Mr. John C. Willever, United States manager cable system; A. C. Kaufman, division cable manager; P. D. Callum, division commercial agent; S. M. Williams, manager of press service; J. F. Nathan, commercial superintendent, and P. J. Casey, special agent. These gentlemen were guests of the association, together with Messrs. E. M. Mulford, division commercial superintendent; W. A. Sawyer, district commercial superintendent; J. A. Hill, division traffic superintendent, and M. W. Hamblin, special agent. Papers were read by Miss N. C. Laughlin, manager of the branch office at 172 Fifth Avenue; Mr. Albert Lister, district cable agent; Mr. J. C. Van Cura, cable agent, and John Simmonds, district commercial manager. A delightful time was had by all. There were over 150 persons present.

A managers' conference of the Western Union Telegraph Company, embracing managers of offices in Maine, New Hampshire and part of Massachusetts, was held at the Congress Square Hotel, Portland, Me., Saturday, April 26, for the purpose of devising ways and means for the securing and handling of summer business. This is the first time that meetings of the fifth district have been held outside the city of Boston, and Portland was the first city to welcome the managers. The meeting was called to order by Mr. C. F. Ames, district commercial superintendent, Boston, Mass., at 2 p. m., and the following speakers were introduced: Mr. P. D. Callum, division commercial agent, New York, who spoke on "Scientific Solicitation of the Telegraph Service"; Mr. A. C. Kaufman, division cable manager, New York, who explained to those present new and interesting features pertaining to the cable business, his remarks being very enlightening and instructive. He was followed by Mr. W. J. Fraser, district cable manager, Boston, who talked on "Cable Solicitation." Mr. E. M. Mulford, division commercial superintendent, New York, thanked the managers for their endeavors in the past and bespoke a continuance of their efforts to increase their receipts, assuring all present that they were being given due credit for their work. After a few remarks by Mr. Ames the meeting adjourned until 6.30, when one of the Congress Square Hotel's famous dinners was enjoyed. During the evening remarks were made by all the managers present, outlining their methods of soliciting business in their respective cities, which developed into a very interesting and instructive debate. Among those present were the following: P. W. Johnson, district commercial manager of Maine and New Hampshire, Boston, Mass.; A. M. Pearson, district commercial manager Eastern Massachusetts; F. D. Byrne, district cable manager, Philadelphia, Pa.; and the following managers: H. H. White, Portland, Me.; J. J. Flanagan, Bangor, Me.; A. D. Allen, Newburyport, Mass.; W. B. Mennealy, Lewiston, Me.; E. M. Fisher, Portsmouth, N. H.; T. H. Harrigan, Gloucester, Mass.; C. A. Pearson, Haverhill, Mass.; C. H. Abbott, Manchester, N. H.; E. I. Herbert, Augusta, Me.; Z. I. Bissonnette, Lowell, Mass.; J. F. Hanrahan, Lawrence, Mass.; W. E. Dickinson, Worcester, Mass.; W. P. Walsh, Rockland, Me.; and J. H. Lang, Lynn, Mass.

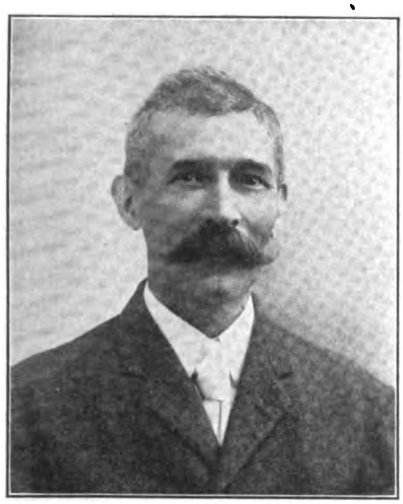
Mr. Loren J. Mink, whose appointment as district commercial manager at Chicago, Ill., was announced in our issue dated May 1, was born in Elgin, Ill., June 30, 1881, and started his career as a telegrapher in his native town, August 7, 1901. Since that time he has filled the positions of operator, manager, chief clerk and district commercial manager at Chicago.

Mr. Harry McKeldin, whose appointment as general traffic chief at Washington, D. C., was announced in our issue of May 1, has been in the service at Washington since 1876. As an expert telegrapher he has a nation-wide reputation, and is a man of genial personality. He has a host of friends who will congratulate him on his deserved advancement. Mr. McKeldin did some remarkably fast press work during the Hayes-Tilden presidential controversy and President Garfield's

Digitized by Google

illness, handling a large amount of press matter on these occasions.

Mr. McKeldin was born in Baltimore, Md., and entered the service of the Insulated Lines Telegraph Company in that city in 1866. In 1872 he became manager of the Southern Atlantic Tele-



HARRY McKELDIN,
General Traffic Chief Western Union Telegraph Company, Washington, D. C.

graph Company at Charleston, S. C., and in 1884 he was appointed night chief operator of the Bankers and Merchants Telegraph Company in Washington, D. C. Mr. McKeldin has worked for about all of the so-called "opposition" companies at different points in the southern and eastern states.

He went to Washington in 1876 and has remained there practically ever since, occupying various positions with the press and telegraph companies, finally settling down with the Western Union.

Redemption of Western Union Bonds.—The Western Union Telegraph Company deposited with the Equitable Trust Company, New York, the sum of $8,560,000 to meet the principal, premium and accrued interest of its $8,000,000 convertible 4 per cent. bond issue, redeemable at 105 May 1.

The New Telegraph and Telephone Buildings in New York.

Work on the new building being erected on Walker and Lispenard streets, New York, to be occupied jointly by the American Telephone and Telegraph Company, the New York Telephone Company and the Western Union Telegraph Company, is progressing rapidly. The steel frame-work has been erected to the sixth story and presents a massive appearance. This building, which was described and illustrated in our issue for February 16, 1911, is planned for an ultimate height of twenty-four stories.

Active work is also going forward on the foundation of the Dey street section of the new building of the Western Union Telegraph Company, to be erected on the site of the present structure at the corner of Broadway and Dey street.

"The Morsel."—We have received a copy of a pamphlet issued under the name "The Morsel" by the commercial department of the Western Union Telegraph Company at Boston, Mass. It is to be issued periodically for the purpose of spreading the gospel of commercialism. The first number contains contributions from several commercial managers in the district, and gives evidence of a lively commercial spirit among the staff. The pages are produced on the mimeograph.

The Cable.

New Japanese Cable.—A new telegraph cable has been laid between Osaka and Tokushima, Japan. This is an inland sea cable about seventy miles in length.

Quick Cable Service.—The Western Union Telegraph Company on May 3 arranged special cable service for the *New York Times* to transmit the story by "Arsene Lupin" of the recent operations and capture of the Paris automobile bandits. The story, consisting of 6,141 words, was put on the wires at London at 2.15 a. m. (New York time) and was sent by the Penzance-Canso cable and the Penzance-Bay Roberts cable, being relayed from these points by cable to Coney Island and thence to the central cable office in New York. The message consumed exactly two hours in transmission, being completed at 4.15. Expert operators were on duty at the relaying points and the whole story was sent over the cables without a break or hitch of any kind.

Obituary.

Andrew Ott, aged 49 years, a well-known telegrapher, died in Cincinnati, Ohio, April 28.

Hubert Child, aged 78 years, a member of the United States Military Telegraph Corps, died at Wichita, Kan., April 29. He was a native of England.

David D. Kennedy, aged 57 years, a former telegrapher and late chief clerk in the passenger department, Baltimore and Ohio Railroad, died at Baltimore, April 29.

E. W. Bradford, aged 75 years, for the past thirty-seven years employed as an operator in the Western Union Telegraph office at Worcester, Mass., died in that city May 6.

J. E. Thomas, aged 90 years, an old-time telegrapher, died in Indianapolis, Ind., April 27. He worked for the Western Union Telegraph Company for over forty-five years, and was retired in 1905.

Jesse H. Bunnell, aged 30 years, son of the late J. H. Bunnell, New York, died recently while on his way from California to New York. He was taken ill on a Santa Fe train and was removed to the hospital at La Junta, Col., where he died a few hours later, supposedly from poison.

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. "Electrical Instruments and Testing," by Norman H. Schneider, with chapters on testing wires and cables and locating faults, by Jesse Hargrave, a well-known and capable electrical engineer, is now being covered in this department. These subjects will no doubt prove of great interest to students, as they are timely and important, and each student should have a copy of the book at hand in order to follow intelligently the study of the subjects under consideration.]

Give the formula for ascertaining the multiplying power of a shunt.

In connecting shunts to the galvanometer what special care should be taken regarding the connections?

Why should the shunt of greatest multiplying power be used first?

What instrument does the modern condenser resemble in principle?

What are the principal elements of a condenser and how are they assembled?

What part of the condenser is called the dielectric?

What substances are used as dielectrics in condensers?

Describe the construction of a condenser.

What dielectric is best for a testing condenser?

What is an adjustable condenser?

How is the capacity of an adjustable condenser varied?

What are keys or switches used for in connection with condensers in electrical testing?

What are the insulated parts made of?

What material is used for contact points? Why?

Why are the hard rubber pillars grooved?

Why do the grooves increase the resistance, and decrease the leakage?

What is a reversing key?

How is a reversing key constructed?

Study the diagram showing the construction and connections of a reversing key.

Why should the reversing key be so connected that the platinum contacts will not form part of the circuit?

What is the feature of the Rymer Jones reversing key?

Why are keys with rubbing contacts preferable to those having striking or abutting contacts?

What is a commutator?

How is a commutator constructed?

Why are the brass contact pieces of a commutator mounted on hard rubber pillars?

What is a "discharge key"?

How many binding posts are there to the Kempe discharge key, and how are they connected?

When the lever is up, what are the connections?

When the lever is down, what are the connections?

President Taft's After-Dinner Speech by Telephone.

The Associated Press and American Newspaper Publishers' Association held a dinner at the Waldorf Astoria in New York on the evening of April 25 and extended an invitation to President Taft to partake of their hospitality and deliver an address. Mr. Taft, however, already had an engagement to deliver a political speech in Boston, but at this point the telephone made its appearance upon the scene and saved the day.

The American Telephone and Telegraph Company, in conjunction with the Western Electric Company, made arrangements which would enable the President to talk directly to the ear of each of the 810 diners. Seven trunk lines were brought in from Boston to the Cortlandt central office in New York, and two from Hot Springs, Va., to enable Premier Burden of Canada to say a few words, thence through seven Western Electric telephone repeaters to bring up the transmission, and then over fourteen trunks to a special switchboard installed in the gallery of the banquet hall.

The table circuits were divided into branches, so that there would not be over 128 receivers on any one, and as each branch was in a "series-multiple" arrangement, tests were made before each speech as a rupture of one wire would have broken up the branch. A special and most successful feature was introduced, whereby two microphones placed in the gallery of the hall conveyed the cheers and applause to the speaker.

The speeches of President Taft and of Premier Burden were heard with marked distinctness, and the successful carrying out of the plans may be regarded as a feat unparalleled in the history of the telephone art. Not only were more receivers in use than ever before, but the transmission obtained was better than it had been possible to obtain previously.

Newspaper Preparations for News of "Titanic" Disaster.—Many of the reporters of out-of-town newspapers who came to New York to handle the news of the "Titanic" disaster on the arrival of the rescue steamer "Carpathia," brought along their own telegraph operators in order that nothing should prevent their papers from having the best of service. On arriving in New York, the reporters had to obtain credentials from the Federal, municipal and police departments before they could get to work, a task that entailed considerable hustling on their part.

High Tension Interference in Ohio.—The Western Union Telegraph Company has complained to the State Utilities Commission of Ohio that the high-tension currents used by the Cleveland, Painesville and Eastern Traction Company interfere with the operation of its telegraph lines, and are a public menace and danger. A hearing of the matter was had at Columbus recently.

CONSERVATION TALKS.—VI.

BY P. KERR HIGGINS, OKLAHOMA CITY, OKLAHOMA.

The Disconnect Problem.

Probably one of the greatest of all wastes in the telephone business is due to premature disconnects or telephones ordered out before a reasonable amount has been earned on the investment. The following is a solution of the problem submitted by the writer. The idea is not new but is an elaboration of a practice frequently employed in private branch exchange contracts.

At first sight the solution may seem impractical but the writer believes that if properly presented by competent commercial men, it would not only prove practical but successful. It would naturally take some time to cover the field, yet every subscriber added would be just that much gain. It is proposed to rent telephones to property owners only; to have the owners collect the telephone rent with the house rent, and allow the owner a percentage for looking after the interests of the company, whether telephone, electric light, water, or other utility. In the case of the telephone in which we are especially interested, benefits would be derived both by the owner and the telephone company.

Let us now consider some of these benefits: On the part of the owner much damage to his property would be avoided, permanent wiring could be put in, more than one outlet being provided for if necessary. His tenant would be able to get prompt service, as the owner on renting his house would simply call the telephone company and notify them that the house was rented. A form of postal card could be used to confirm the telephone message, and this postal card would furnish the data for directory, etc. The owner would not be responsible for rent when the house was vacant. All that would be required of the owner would be permission to wire his property, and a contract for telephone service subject to terms agreed upon, such as no charge when property is vacant, commission on collections, charges for moving telephone, notifying company when premises are vacant or rented, privilege of removing telephone at option of the company, etc.

On the part of the telephone company the advantages are almost too numerous to mention, but a few may be mentioned.

(1) Disconnects would be reduced to a minimum, for people would be more liable to take and keep a telephone if it was a part of the rent, than otherwise: (2) Collections would be more easily handled and would reduce uncollected per station; (3) Equipment could be arranged on a permanent basis, e. g., a desk stand could have a plug and jack attachment, and wall sets could be installed in a cabinet flush with the wall. This would be of great advantage to the telephone company and a convenience to the subscriber, since when the telephone was not in use, he could pull the plug and lock the telephone up in his desk or close the cabinet, as the case may be. This would save him much annoyance from the non-user, and the company disputes over toll calls, etc., thus eliminating considerable loss of revenue; (4) It would reduce to a minimum the accounting for in the case of buildings, flats, hotels, etc., only one account would be necessary, hence it is safe to estimate that the number of subscribers' accounts would be cut almost in half. There are many other equally important benefits, but these will serve to illustrate some of the advantages. There are practically no disadvantages to the system and the only serious question involved is how successful we would be in interesting owners of property.

An objection might be raised that having a number of telephones not in use and tied up in empty houses would be a poor investment, but since we reserve the right to take out telephones when necessary, the depreciation would be less with the instruments hanging on the wall than when kept in storeroom, as at present. A record of all such inactive telephones would be kept by the plant department and used to the best advantage possible.

Much damage is done to telephone sets by improper handling on installation wagons, etc., and this would be cut down to the minimum, if telephones are left on premises until absolutely necessary to use them. If the owner can afford to risk his plumbing, etc., in an empty house, surely we should be willing to risk our small investment.

This method of handling the disconnect problem might be gone into in more detail, but the object of this article is to start thought along these lines, and it is the belief of the writer that if this method is adopted, the problem will soon be a thing of the past, much waste will be prevented and revenue and efficiency increased very materially.

The plan submitted is a radical move but the writer believes that only a radical change of method in securing contracts will bring desired results and insure a complete cure.

The following remedy is suggested as a palliative one, and would materially improve matters, be less radical, and probably more quickly assimilated by the public, namely:

Insert in all future contracts a proviso, that, in the event of the patron ordering his telephone taken out for other reasons than failure of the company to comply with its provisions, before the expiration of one year from date of installation, the patron would be liable for the cost of installation and take out, in proportion to the time the telephone has been in service, e. g., telephone has been in three months, he would be liable for 9/12 of the total installation and take out charges. The total of these charges being inserted in the contract so that the patron would know just where the charges would be.

These figures can easily be made at the time of making the contract and may fit each case, or an average cost could be agreed upon.

At first I was inclined to think that a maximum amount should be inserted, but to fit all cases and be fair to all parties, I believe it is best to leave the amount to be filled in .

Digitized by Google

There should also be inserted in all contracts a proviso, permitting the telephone company to charge for moving a telephone when not in constant use in same location one year. These provisos are not only very necessary from a company viewpoint, but as a part of our duty to conserve the interests of the public, whose servants we are.

Radio-Telegraphy.

Mr. W. W. Bradfield, manager of the English Marconi Wireless Telegraph Company, London, is in New York on business in connection with the service. He will return to England on the "Mauretania" May 22.

Signor Guglielmo Marconi sailed for Europe April 30 on the North German Lloyd steamer Kaiser Wilhelm II. Mr. Marconi arrived in New York March 14. Since that time he has been kept very busy. He inspected the Marconi transatlantic station at Glace Bay, N. S., delivered a lecture April 17 before the New York Electrical Society on recent developments in wireless telegraphy, and was for over a week a witness before the Senate Committee in New York and Washington investigating the "Titanic" disaster. He expects to return to New York in the fall.

Wireless Between Rome and Tripoli.—Direct wireless communication between Rome and Tripoli was opened April 15.

Marconi Stock Increase.—The Marconi Wireless Telegraph Company of America has filed a certificate with the secretary of state of New Jersey showing an increase in its capital stock from $1,622,500 to $10,000,000.

Wireless Equipment Wanted.—Bids are invited by Captain R. J. Burt, Signal Corps, U. S. A., Washington, D. C., for four 1-kw. wireless telegraph equipments for installation in land stations. Bids will be received until May 25.

Violations of the Wireless Act.—The Federal grand jury at Norfolk, Va., on May 8 found indictments against the masters of five British steamers for the violation of the act requiring vessels to be provided with wireless apparatus.

Authority Over Wireless Stations.—A federal wireless regulation bill was passed by the United States Senate May 7 giving the Secretary of Commerce and Labor authority over all wireless stations in the United States, and provides for licensing them. The measure complies with the general wireless treaty recently ratified by the Senate.

Wireless News from Ships at Sea.—Mr. Willis C. Pratt of New York states that he is working in conjunction with the Marconi Wireless Telegraph Company to have a competent and trained newspaper man on board every ocean steamship to report to land by means of the wireless any happening of interest. So far he has not been able to get an answer from the steamship owners on the proposal for the sending of news without the censorship of the captain.

Opposes Wireless Regulation.—Mr. John Stone Stone, of Boston, Mass., the well-known wireless-telegraph inventor, is opposed to government regulation of wireless telegraphy, and he advises against the United States subscribing to the Berlin wireless treaty. Such action or the passage of bills now before Congress establishing government regulation would, he says, check progress in a new art which is now daily advancing in flexibility, in range and in importance.

Col. Wilson's Testimony.—Col. Christopher C. Wilson, former president of the United Wireless Telegraph Company, appeared before United States Commissioner Alexander in New York for examination in the bankruptcy proceedings of the company. He testified that the only personal property he had was a watch. He denied specifically that he had any life insurance or any equity or beneficial interest in any property anywhere. His real property in Long Beach, Cal., and Denver was mortgaged and sold to pay for his lawyer's fees, he said. He received altogether between $600,000 and $800,000 from the sale of United Wireless stock, all of which he has expended in personal expenses and mining speculations.

Two Wireless Operators on Steamers.

The United States Senate on May 1 passed a bill requiring that two or more wireless operators be employed on every ocean-going vessel carrying one hundred persons, whether passenger or crew, an operator to be on duty all the time, night or day, and the wireless apparatus to be capable of transmitting and receiving messages over a radius of at least one hundred miles. The bill goes into effect July 1, 1912.

Proposed Memorials for Phillips, the Titanic's Wireless Operator.

The Maritime Association of the Port of New York on April 30 appointed a committee to solicit subscriptions for a memorial to Jack Phillips, the wireless operator who lost his life on the steamer "Titanic" April 15. Mr. C. C. Galbraith, general manager of the United Wireless Telegraph Company, now a part of the Marconi system, was designated to head the committee which will have charge of the raising of funds for this purpose.

Mr. Harold Bride, the surviving wireless operator of the lost steamer "Titanic," was the first subscriber to the Phillips Memorial Fund, contributing $25 thereto. Mr. Bride sailed for England May 4, on the steamer "Caronia."

A fund is being obtained in England by popular subscription to erect a monument in Phillips' memory in his native town, Godalming, England.

The telegraphers of the Madrid, Spain, office, as announced May 1, will place a portrait of Phillips in the main operating room, and they propose to ask the International Telegraph Bureau at Berne, Switzerland, to take suitable action toward perpetuating the memory of the brave young operator.

Dedication of the Telegraph Monument.

The monument commemorating the sending of the first train order by telegraph was dedicated at Harriman (formerly Turner), N. Y., May 2, under the most favorable circumstances. The day was a beautiful one; the air was balmy and the surrounding country was garbed in its spring loveliness. The scene at the station was charming and those who were fortunate enough to be present at the ceremonies were deeply impressed with the glorious surroundings. Nature, as well as man, contributed to make the event one of enjoyment.

Two special trains left the Jersey City terminal of the Erie Railroad at 10.30 a. m., with an enthusiastic party of about 400 guests, including many distinguished gentlemen in the telegraph and railroad worlds, and arrived at the Harriman station after a pleasant run of a little more than an hour.

The party repaired at once to the stand especially erected near the monument, where the ceremonies were to be conducted. Around the monument were gathered several hundred townspeople who had come to witness the interesting event. Over a hundred school children, boys and girls, each waving a little American flag, marched to the grounds and formed a semicircle about the monument, where they assisted in the singing during the exercises. The little girls were dressed in white and added much charm to the animated scene.

The guests' stand was tastefully decorated with bunting and colors, and all the houses in the neighborhood were likewise adorned.

One of the prettiest tributes to the occasion was

FIG. 1. THE MONUMENT.

the stationing of four New York messenger boys around the base of the monument, one on each corner. They were manly, intelligent young fellows, and stood as guards of honor all through the ceremonies, removing their caps as the patriotic airs were sung.

After the guests had been seated, Chairman E. P. Griffith called upon the Rev. J. Holmes McGuinness, rector of Arden, to open the ceremonies with prayer. At the conclusion of the prayer, "America" was sung by the audience, led by Mr. Edson S. Miller, cornetist, after which Mr. Griffith gave a brief history of the inception and development of the project, culminating in the finished memorial.

Mr. Henry D. Estabrook, orator of the day, was then introduced. His address was highly inter-

FIG. 2. VIEW OF MONUMENT AND HARRIMAN STATION.

esting as well as appropriate and he handled his subject in a masterly and logical manner. He gave a sketch of Charles Minot, and reviewed the circumstances that led to the sending of the first train order by telegraph. The engineer refused to obey the order and Mr. Minot himself took the throttle and ran the train to Goshen, as his own order directed. Mr. Estabrook's fine sense of humor was shown in the many anecdotes and humorous references judiciously employed throughout his address, and his audience was kept in an attentive and happy frame of mind throughout.

At the conclusion of Mr. Estabrook's address, Miss Gertrude M. Griffith, escorted by Mr. David Homer Bates, advanced to the monument and, as the audience was singing the "Star Spangled Banner," and the school children waved their flags, unveiled the bronze tablet which had up to the moment been hidden by an American flag.

Mr. David Homer Bates then, in a very interesting address, presented the monument to the Erie Railroad Company.

He told of a recent call upon Mr. Andrew Carnegie, during which he asked Mr. Carnegie to tell about his first experience in the movement of trains. Mr. Carnegie told of how he knept trains moving on the Pennsylvania Railroad one stormy morning in the winter of 1854. He was then 18 years of age. Mr. Thomas A. Scott, superintendent at Pittsburgh, did not reach the office on account of the storm, and Mr. Carnegie had to answer inquiries from the crews of the stalled trains. He took the risk of signing Mr. Scott's initials to telegraph train orders and soon had the trains moving. Late in the afternoon Mr. Scott came hurriedly into the office exclaiming, "Andy, where are the freights?" Young Carnegie pointed out the window, as one of them was pulling into the yard, and explained that the others were coming along. "Mr. Scott," he said, "I couldn't

Digitized by Google

help it. The crews were nearly frozen, and I signed your initials to the orders." Next day in talking about the incident to Mr. Franciscus, the freight agent, Mr. Scott said, "Charlie, do you know what that little Scotch devil of mine did in that storm yesterday? Before I reached the office he signed my name to train orders all day, and got the trains through safely, and all of the train

FIG. 3. ORIGINAL TURNER STATION, 1848.

men thought I was at the key myself sending the orders."

"After that," said Mr. Carnegie, "Mr. Scott left the running of the trains almost entirely to me." This was Mr. Carnegie's first experience in running trains by telegraph.

Mr. Bates referred in complimentary terms to the generosity of Mrs. E. H. Harriman in providing the stone for the monument and bearing the cost of its carving and setting. He also complimented Mrs. Harriman's representative, Mr. C. T. Ford, who erected the speakers' stand and had general supervision of the planning of the arrangements at Harriman for the dedication.

The address of acceptance was made by Mr. George N. Orcutt, general attorney of the Erie Railroad. Mr. Orcutt stated that the greatest improvements in railroading came with the introduction of the telegraph. It was fitting, he said, to have this monument erected along the line of the railroad which was first to recognize the value of the telegraph in railroad work. He closed his address with an eulogistic reference to the late E. H. Harriman, who, he stated, had done more than any other individual in the development of the American railroad.

The "Ode to Morse" was then sung by the audience, led by its composer, Mr. Marion H. Kerner, after which the benediction was pronounced by Rev. J. Holmes McGuinness, and thus the interesting exercises were, at 1.10 P. M., brought to a close.

The party then returned to the train and reached New York a little before three o'clock. A lunch was served on board of the train during the return trip, and all expressed themselves as highly pleased with the events of the day and congratulated the committee on the successful manner in which the programme had been carried out.

The monument stands a short distance west of the station and forms a conspicuous object on the landscape. It is classic in design and was greatly admired for its massive elegance. The committee, with the generous assistance of Mrs. E. H. Harriman, have good reason to feel proud of their achievement.

A second special train conveying the officials of the Erie Railroad to Chicago was stopped and held at Harriman in order to permit these gentlemen to attend the ceremonies. President Underwood occupied a seat on the stand next to Mrs. E. H. Harriman, and both showed great interest in the proceedings. Mr. Thomas A. Edison also occupied a seat on the speaker's stand and at the conclusion of the ceremonies met many old friends who were in the party. He was introduced to the audience by Chairman E. P. Griffith, and bowed his acknowledgment of their applause. Mr. Edison was accompanied by his daughter.

Among those who occupied seats on the speaker's stand besides the monument committee and speakers, were: Mr. F. D. Underwood, president, and all the executive officials of the Erie Railroad; Mrs. E. H. Harriman, Arden, N. Y.; Mr. Thomas A. Edison and daughter, West Orange, N. J.; Col. R. C. Clowry, New York; Mrs. G. S. Minot, Brookline, Mass., niece of Charles Minot; James Merrihew and wife, New York, and 100 others.

The press was represented as follows: B. B.

myer and wife, E. W. Wade and wife, A. T. Zabriskie and wife, Passaic, N. J.; J. C. Haring, Piermont, N. Y.; S. L. Van Akin and wife, Syracure, N. Y.; W. C. Banks, D. H. Bates and wife, D. H. Bates jr., Miss Batsford, T. M. Brennan, F. W. Brindle, C. H. Bristol, wife and daughter, R. Bunten, P. J. Casey and wife, Col. R. C. Clowry, R. H. Corson, F. G. Curry, Mrs. Chas. Davis, W. J. Dealy, F. N. Dowler, L. Dresdner, A. N. Dugan, T. H. Ellett, H. D. Estabrook, L. B. Foley, M. Green, E. P. Griffith, wife and daughters Lura and Gertrude, Mrs. Bert Griffith, W. E. Harkness and wife, Miss Millie Heuser, G. W. Hickey, G. R. Hill, E. E. Hudson, Gardner Irving, W. L. Ives, B. A. Kaiser, Charles Keck, M. H. Kerner and wife, J. W. Lewis, Mrs. Eleanor Loring Lord, Wm. Maver, jr., and wife, James Merrihew and wife, M. J. O'Leary, G. N. Orcutt, Mrs. E. Peak, C. D. Reed, F. J. Scherrer, C. L. Seeley, wife and son, C. N. Sigison, C. M. Smith, E. E. Taffany, J. B. Taltavall, wife and daughter Florence, A. B. Taylor and wife, J. B. Van Every, T. B. Van Nortwick, A. D. Walters and wife, E. M. Weaver, L. S. Wells, J. C. Willever, J. W. Young, New York.

A laughable incident occurred as Mr. Orcutt began speaking. As he started, a train arrived at the station blowing off steam and keeping up a constant bell ringing. The noise caused him to halt until the train resumed its journey. After it had proceeded far enough away, as he thought, he endeavored to resume his speaking and had hardly uttered half a dozen words when he was again interrupted, this time by a loud whistling by the same train. The incident created a great laughter, but Mr. Orcutt turned it to his advantage.

Mr. E. P. Griffith, chairman of the Monument Committee, is deserving of much credit for the masterly way in which he conducted the affairs of the undertaking, from beginning to end. He has been an active and watchful worker all through the period of development and took the lead in the work of arousing interest in the project and managing the collecting of subscriptions. He originated the idea, and the entire enterprise was skillfully managed by him, and, finally, when the supreme moment arrived he showed himself to be as skillful as a master of ceremonies as he was a manager. Much credit is also due to his fellow-committeemen, who, by their advice, encouragement and active assistance aided him in the achievement of such successful results. The members of the Monument Committee present at the unveiling, besides Mr. Griffith, were W. J. Camp, David Homer Bates, J. B. Taltavall and F. J. Scherrer.

Since the last acknowledgment of contributions, two more remittances have been received. The fund now stands as follows: Previously acknowledged, $2,325.09. F. A. Stumm, Ridgewood, N. J., $1.00; Frank J. Howell, Corning, N. Y., $5.00. Total, $2,331.09.

In sending his contribution Mr. Howell writes from Corning, N. Y.: "I well remember in the early '60's of Charles Minot, the red-faced, black-haired superintendent that would step out from his special car to our (then) new Pine street depot, over the platform to the Erie telegraph office, for his telegrams. Sometimes in his car a few Corning boys would be favored with a trip to New York City and return at his expense. They enjoyed such joy-rides as well if not better than 'Huckleberry Finn' ever enjoyed any of his adventures. In 1860 Mr. Minot built a new stone station in Corning at Pine street and Erie avenue. In the upper west end story, I learned in 1864 on a brand new Tillotson register, the first symbols of the Morse art, from operator W. H. Kinney, now of Mansfield, Pa. The upper story of the station burned a few years later, and it is a now a humble one-story historical monument to the late Charles Minot."

Wireless Facts From Mr. Marconi.

The following interesting facts are gleaned from the testimony of Signor Guglielmo Marconi before the Senate Committee in charge of the investigation into the "Titanic" disaster.

It is against the regulations of the Marconi Company for its operators to act as newspaper reporters while on duty.

In England government control aims to avoid interference with wireless messages by providing different wave lengths for different kinds of service. Thus, the Post Office Department, in charge of the service, has one wave length for domestic messages and another length for the Continent. The army and navy stations have each a wave length of their own. A scientist wishing to experiment is also assigned a special wave length, and is required to practice in the part of the country where he will not interfere with the service of similar length.

The contract between Mr. Marconi and the English Government is signed by the Postmaster General, but is still pending for the approval of Parliament.

The contract runs for twenty-eight years, but the Government may cancel it at the end of eighteen years. It provides, Mr. Marconi said, that within two years we shall erect stations in England, India, Cyprus, South Africa, Singapore, and other places. We are paid a lump sum for the erection of each station, but before acceptance must satisfy requirements as to speed, effectiveness, and reliability. "I am required to run the stations for six months after their erection," he said, "then for ten years the Government pays me 10 per cent. of gross receipts from all messages."

The wireless station at Cape Race, N. F., can send reliably a message 400 or 500 miles by day and 1000 miles or more by night.

The greatest distance on record covered by a wireless message is 6000 miles, between Buenos Aires, Argentine Republic, and Clifden, Ireland.

Wireless operators on transatlantic steamers receive in England from $4 to $12 per week, with board and lodging.

Standards of Telephone Transmission.

BY B. GHERARDI, ENGINEER OF PLANT, AMERICAN TELEPHONE AND TELEGRAPH COMPANY, NEW YORK.

In a paper read recently before the Telephone and Telegraph Society of New England, at Boston, Mass., the author said that telephone transmission is ordinarily stated as being equivalent to transmission obtained over a given number of miles of No. 19 B. & S. gauge cable having defined constants and with given terminal conditions. In other words, we use No. 19 gauge cable as our measuring rod. The type of No. 19 gauge cable used is not the No. 19 gauge cable which we are now employing so extensively, but is the No. 19 gauge cable which was used a number of years ago when the standards were established, and which is of somewhat lower capacity than the cables now employed. The transmission efficiency of our present No. 19 gauge cables is about ninety per cent. of the standard No. 19 gauge cable used for measuring purposes, that is, nine miles of the present cable are equivalent to ten miles of the standard.

When we speak of service which from a transmission standpoint has an efficiency of eighteen miles, what we mean is that the talk is equal to that obtained over a circuit consisting of eighteen miles of the standard low capacity No. 19 gauge cable already referred to when there is connected at each end of it a standard common battery substation set applied with current from 24-volt storage batteries through No. 25-A repeating coils over zero subscribers' loops. The standard of transmission usually adopted for local service is eighteen miles. One of the combinations which would give this standard which might occur in service would be—two subscribers, each having subscribers' loops of No. 22 gauge wire three-fourths of a mile long, connected together at the two ends by the standard "A" and "B" cord circuits and a trunk line between the two offices of seven miles of No. 22 gauge cable or ten miles of No. 19 gauge cable or twenty-two miles of medium loaded No. 19 gauge cable. When the subscribers' loops are longer than the figures assumed the trunk line must be shorter in order to give the same transmission. For example, if the subscribers' loops are each equivalent to two miles of No. 22 gauge cable the limiting lengths for the trunk lines to give eighteen-mile transmission are—about three miles for No. 22 gauge cable, four miles for No. 19 gauge cable, unloaded, and eight miles for No. 19 gauge cable medium loaded.

The standards of transmission very generally used are:

For local service.....18 miles
For suburban toll service .....25 miles
For long haul toll service .....30 miles

Large sums of money are being spent annually for the construction of plant. A considerable portion of this is spent to obtain good transmission; for if we were willing to be satisfied with a plant which did not talk so well we could plan so that the plant could be built more cheaply. We must not forget, therefore, that substantial expenditures have been made to get transmission and that all of the departments concerned in the design, construction, maintenance and use of the plant must contribute their part to the getting of the most economical results.

In reference to the maintenance of the plant, there are many features which react upon the transmission:

The maintaining of all lines so that they are quiet is important. Even a small amount of noise on a line substantially impairs its transmission efficiency as far as the results obtained are concerned. A very moderate amount of noise—an amount which is often considered to be entirely unobjectionable—will impair transmission by as much as three or four miles of cable.

Attempts are sometimes made to improve noisy lines by the insertion of "bug traps" rather than by removing the cause by well known methods. We know of cases where "bug traps" have been inserted to remove noise, which traps have impaired transmission by as much as ten miles. The principal effect of the "bug trap" was to remove the noise by removing the transmission.

The making of unauthorized modifications of standard apparatus or circuits to improve some operating feature without regard to its effect on transmission. A common example of this is the opening of the non-inductive winding on series relays to improve the signaling.

The failure to properly maintain repeating coils, retardation coils, etc., so as to see that coils having a considerable number of short circuited windings in them are removed from service. Such short circuited windings do not usually affect the signaling efficiency of the circuits, and are too frequently ignored by those maintaining the plant.

Dry Cells.

At the meeting of the American Electrochemical Society, in Boston, Mass., April 18, 19 and 20, a paper on the performance of dry cells was presented by Mr. Carl Hambuechen. The author stated that the three important characteristics of dry cells by which merit is judged are the short-circuit current, the shelf life and the watt-hour output. The latter is of most importance, and the first is of least importance, but is, perhaps, the most commonly used. Consequently some manufacturers have, during the past few years, developed cells which give an increased flash test, and curves were given showing this general increase, which amounts to over 50 per cent. This has not been accompanied by any improvement in durability, shelf-wear or capacity. The adoption of better methods of testing will probably result in more attention being given to long life and energy output. The latter are especially desirable for telephone and alarm service and the use of cells for emergency purposes. Curves were given showing the average shelf life as determined by the customary flash test. Cells having the highest initial flash deteriorate most rapidly. However, a falling off in the flash test does not necessarily indicate a corresponding reduction in useful capacity.

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

May 16, 1912.

Testing and Developing Inventions.

The man who invents something for the first time is naturally an enthusiast, so far as his invention is concerned, and he cannot understand why everyone does not appreciate the importance and value of his invention as he does himself. The best of us are, to more or less extent, narrow-minded, and we usually look at a subject from our own viewpoint, overlooking the fact that others look at the same thing in a different light.

Many inventors complain that they are handicapped by the telegraph companies and electrical concerns, who, they assert, place every obstacle in the way of the development of their ideas. We have taken the trouble to investigate the facts in some such cases, and we find that every reasonable encouragement is given the inventor by the companies. Their experts first determine whether the principle involved is correct, and if there is anything new in the supposed invention. If it is wrong in principle and contains nothing new, it would of course be a waste of time to make any further investigation or test, and this is the reason why would-be inventors in many cases get the impression that their inventions do not receive the proper recognition.

The companies are always on the lookout for new things and it is to their best interest to encourage inventors, but inventors are seldom impartial judges of the value and patentability of their own inventions. Frequently they produce something that has already been accomplished and possibly abandoned, and because they are ignorant of what others have found out before them they assume that they are the first on the ground.

Inventors are proverbially poor business men, and even if they do produce something new they place upon their invention a valuation that is out of all proportion. Trivial inventions are valued by them at thousands of dollars; sometimes the figures run into the millions. They are so completely dominated by the idea that they have made an important discovery that all else is blotted out of their minds and they lose control of their better judgment.

One inventor who made bitter complaints had actually been favored by the telegraph companies to the extent of loaning him on Sundays the use of long circuits for experimental purposes. He tested his invention himself and because it did not fulfill his expectations he blamed the companies for its failure.

Some inventors present ideas to the telegraph companies and ask the latter to give them a practical test and develop the apparatus at their own expense, and after this has been done ask a fabulous sum for the invention which sometimes proves to be not their own. Then again if the inventor wishes to secure an opinion as to the value and utility of his invention he asks the telegraph companies to pass upon these points, thus placing the burden of an investigation upon the telegraph interests.

Inventors should approach the companies in a businesslike manner, and should be sure of their ground before opening negotiations. The telegraph companies, as we have already pointed out, are favorably disposed toward inventors, and are usually willing to aid in the test if the invention appears to have merit, but the inventor should not ask too much of the companies. The latter have expert advice at their command and can soon arrive at a correct conclusion with respect to the invention, whereas the inventor is usually inexperienced in such matters and should not assume to tell the companies what is already known to them, and thus in many cases jeopardize their own interests.

Lessons From the Titanic Disaster.

Our present-day knowledge is the result of experiments, successes and failures, but largely failures. Failure to immediately achieve or realize what we hope for is one of the most profitable lessons humanity can experience, because it teaches what to avoid in order to gain our end.

The Titanic disaster, although a terrible event in itself, has taught the world many important lessons, which will bear fruit for the benefit of the living and those to come after.

The lessons that chiefly concern the readers of this publication relate to the conduct and operation of wireless telegraphy on shipboard, not only in times of emergency but at all times.

In the advancement of many large human activities the principle of being prepared at all times to meet emergencies is well recognized and established. Thus we find that nations in times of peace prepare for war; business enterprises carry insurance in one form or another against possible loss, and the running of trains on modern railways is conducted on the theory that there is

Digitized by Google

danger ahead unless the signals show that the track is clear.

The Titanic disaster has publicly revealed the fact that wireless telegraphy has many weak points, as well as many strong ones. The fact, however, that it has weak points is no condemnation of the system, for nothing that man has ever devised is perfect. As the weak parts of a machine are revealed they are replaced by stronger parts, and this is true in all lines of progress—as we discover faults we correct them.

The importance of having some one on duty at the wireless instrument every moment of time was strongly emphasized in connection with this awful event, although it has been pointed out before. Where there is only one wireless operator on shipboard there must necessarily be periods of time when the wireless is without attention, because the operator needs rest.

Unattended wireless service is certainly a weak point and steps have already been taken by the Federal authorities to compel the employment of two operators on certain classes of steamers. There should be no distinction shown, however. All steamers, freight, passenger and others, carrying wireless equipment, should be placed on an equal footing in this respect, for it is just as possible for a freighter or even a tug to need assistance and be of service in emergencies as for a passenger steamer. The lesson has been a costly one, but perhaps it was necessary in order to bring the world to a realization of the folly of neglecting the most important requirement of ocean wireless telegraphy.

Considerable complaint has been made of the domineering attitude of some of the wireless operators concerned in this tragic event, and it has been suggested that no one but men of mature years, capable of exercising sound judgment at all times, should be employed in the wireless service. This brings up a point of vast importance, which, however, cannot be settled in an off-hand manner. The principle is all right, but the practice of it presents many difficulties, moral and commercial. It is not fair to condemn all wireless operators because a few have acted in an arbitrary and impulsive manner, yet on the other hand, every means should be adopted to employ men not only because they have passed an examination as operators, but because they measure up as well to the standard of moral qualities necessary to fit them to hold such important positions.

The matter of interference is one of the most pressing that has been brought forward in this connection. Some international arrangement seems to be the only practical solution of this problem. There certainly should be some sort of an understanding for guidance in times of emergency, and no doubt this important matter will receive due attention at the London radio-telegraph conference next month.

It is evident from the experiences that wireless telegraphy has just passed through that there is much room for improvement. But the situation is not by any means discouraging. International agreements and inventive genius will certainly bring about the much desired relief from the dangers which have beset the past and no doubt wireless telegraphy on steamers will undergo a refinement and development that will gain for it the confidence of the traveling public that it is entitled to, in place of the feeling of lack of faith in it that seems to prevail to some extent just now.

The Selector Situation.

The announcement was made in our issue dated May 1 of the consolidation of several railway equipment concerns which will be of special interest to railway telegraph and telephone departments. The new corporation, the General Railway Equipment Company, represents the combined interests of various well-known selector manufacturing companies and the consolidation of these separate concerns means greater economy in industrial operation and increased efficiency of the product. The experieince, technical skill and manufacturing facilities of the separate companies combined in one going concern cannot fail to be productive of the best results and meet the requirements of modern railway operation which demand only the best equipment.

Railway managers will experience greater satisfaction in dealing with a concern of larger responsibility than with smaller companies acting separately and individually, each handicapped by the burdens resulting from divided effort and rival claims. The ample capital at the command of the new organization is an assurance of the strength of the sponsor for the apparatus offered and of its ability to execute contracts involving the installation of complete standard equipment.

The new company will be the only one in the United States making a specialty of manufacturing and installing selective and telephone and other electrical equipment for railroad uses. Its product is covered by broad patents. It is also understood that the company will act as sales agent in the United States for important foreign manufacturers whose equipment is already well known in this country.

Posts and Telegraphs in Germany.—The published statistics of the German Empire show that the cost of operation, maintenance, and extension of the German system of posts and telegraphs was as follows during the fiscal years named: 1911, $153,202,218; 1910, $148,157,180; 1909, $146,086,089. The number of telegrams received for transmission in Germany in 1909 was 46,802,000 and the number delivered in the same year was 44,800,000. The number of messages received in 1905 was 42,647,000 and the number delivered in that year was 41,479,000.

A correspondent asks to know which inventor has "created more talk than any other person in history." The man who invented the telephone is certainly entitled to the credit.

Course of Instruction in the Elements of Technical Telegraphy—XV.

(*Copyrighted.*)

(*Continued from page 280, May 1.*)

[We began in our issue for October 16, 1911, the publication of a course of instruction in technical telegraphy. The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and is divided into chapters, following one another in logical order.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases, and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.]

Example: To find the resistance of a branch of a derived circuit when the fall of potential through it is 5 volts and the current in the branch .25 ampere.

Solution:

$$\frac{E}{I} = R, \text{ or } \frac{5}{.25} = 20 \text{ ohms.}$$

Example. To find the resistance of a branch of the dividing and uniting points of the branches of a derived circuit when the joint resistance of the branches is $2\frac{6}{7}$ ohms, and the total current in all the branches 1.75 amperes.

Solution:

$IR = E$ or $1.75 \times 2\frac{6}{7} = 5$ volts.

NOTE.—In the last example since the potential falls through all three branches, R, in the equation, must evidently be the combined resistance of the branches, and I, the combined or total current strength.

If the joint resistance of two wires in parallel be known, and the separate resistance of one of the wires, the resistance of the other may be found.

Example. The joint resistance of two wires in parallel is 50 ohms. The resistance of one of the wires is 75 ohms, find the resistance of the other.

Solution:

Let x stand for the unknown resistance; then by the rule for finding the joint resistance of two wires in parallel,

$$\frac{x \times 75}{x + 75} = 50.$$

Clearing the equation of fractions,

$$75x = 50x + 3750$$
$$25x = 3750$$
$$x = \frac{3750}{25} = 150 \text{ ohms.}$$

A thorough comprehension of the laws relating to derived circuits, is of the utmost importance, as they form a feature of the Duplex and Quadruplex arrangements, and in fact enter largely into every department of technical telegraphy.

In dealing with all problems relating to Current, Resistance, and Potential, remember that Ohm's law, $\frac{E}{R} = I$, involves the total circuit resistance, the total current strength, or the current in the main circuit, and the fall of potential through the total circuit resistance.

Also, that $\frac{E}{R} = I$ involves the resistance of part of the circuit, the fall of potential through that part, and the current in that part, whether the part be the branch of a derived circuit or a section of the main line.

Parallel circuits are formed in practice when two or more wires are connected to one battery, or when a wire touches another wire, or tree, or other object connected with earth, or earth itself.

If a wire were connected to a telegraph line at an insulator, and led down the pole to ground a derived circuit would be formed, the earth making the second connection for although the resistance of the materials of which the soil is composed may be comparatively high, yet the area of the conductor is so large that the resistance actually offered is reduced to nothing, provided always that the soil in the immediate vicinity of the "ground" conducts well.

Example. Two circuits are connected to one battery consisting of 50 gravity cells. The current given out by the battery is .1 ampere. The resistance of one circuit is 500 ohms.

(1) Find the resistance of the other circuit.

(2) Find the current in each circuit.

(3) If the 500 ohm circuit be open how is the current in the other circuit affected?

Solution:

(1) Here we have the total potential and the total current, therefore by applying $\frac{E}{I} = R$, we will obtain the total resistance of the circuit.

$$\frac{50}{.1} = 500 \text{ ohms.}$$

Since there are 50 cells in the battery there is an internal resistance of 100 ohms which is included in the total circuit resistance. To obtain the resistance of the circuits alone we must therefore subtract the battery resistance from the circuit resistance: 500 — 100 = 400 ohms.

The two circuits being in parallel, this resistance of 400 ohms is the joint resistance of both circuits, and as one of them has 500 ohms resistance, we have, by letting x stand for the other.

$$\frac{x \times 500}{x + 500} = 400 \text{ ohms.}$$

$x = 2000$ ohms, or the required resistance.

Solution:

(2) The current from the battery is .1 ampere. The separate resistances of the two circuits are 500

Digitized by Google

and 2000 ohms, therefore the resistance ratio is as 500 is to 2000, or as 1 is to 4.

As the current divides between the branches of a derived circuit inversely as the respective resistances of the branches, it follows that if the current were divided into 5 equal parts, 4 of these parts, or $\frac{4}{5}$ of the current, would go by the 500 ohm branch, and 1 part, or $\frac{1}{5}$ of the current, by the 2000 ohm branch.

$\frac{4}{5}$ of .1 = .08 = current in 500 ohm circuit.

$\frac{1}{5}$ of .1 = .02 = current in 2000 ohm circuit.

Or this may be solved as follows: The circuit resistance is 500 ohms. The battery resistance is 100 ohms. The potential therefore at the junction of the battery and wires has fallen $\frac{1}{5}$, since $\frac{100}{500}$ = $\frac{1}{5}$ of the current resistance has been overcome.

$\frac{1}{5}$ of 50 = 10 volts.

The potential which falls through the circuits is consequently 50 — 10 = 40 volts.

To find the current in the branches $\frac{E}{R} = I$.

$\frac{40}{500}$ = .08 amp.

$\frac{40}{2000}$ = .02 amp.

Solution:

(3) If the 500 ohm circuit be open, the other branch will receive the entire current from the battery, which, assuming a perfect line insulation, is the same in all parts of the circuit.

The resistance in circuit is now 2000 + 10 = 2100 ohms; therefore, to find the current, $\frac{E}{R} = I$

$\frac{50}{2100}$ = .023 ampere.

The current has risen from .02 to .023 ampere in the 2000 ohm circuit by the other circuit being opened.

Determining Resistance for Station Selectors.

BY W. J. DOHERTY, MILES CITY, MONT.

With reference to the various methods of determining the required added resistance to be placed in series with station selectors, in any built-up combination, where all the selectors are to receive equal volume of current, permit me to offer an extremely simple method applicable to any circuit, regardless of the resistance of the selector used.

Referring to the illustration, take as an example, a 16,000-ohm selector. Assign to each section between stations a number, beginning with the distant station section as 1, the next, 2, 3, and so on consecutively.

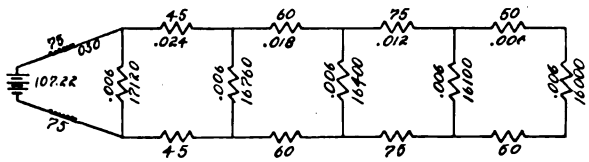
Multiply the line resistance (both sides) by the number of the section, in each case, adding it to the previously derived value.

In the illustration 1 × 100 = 100, which, added, to 16,000, the selector value, gives 16,100, or first value. To this add twice the resistance of the next section—300 ohms—giving 16,400; for the second station, proceed in like manner, adding to this three times the resistance of the next section, 360 ohms, giving 16,760 for the third section, and so on. The current values are similarly obtained. Merely write the required amount to operate the instrument in the last selector, multiplying this amount by the number of the section for each new line current as shown.

Then to obtain the total voltage required, where coils or other resistance are inserted between the main battery and the line, it is only necessary to multiply the last resistance by the current. To this must be added the product, which, in this case is 4.5 volts, making the total voltage required 107.22 volts.

[Regarding this method of computing tapering resistances, Mr. G. K. Heyer of the Western Electric Company, New York, says:

"We have been using this method of figuring the tapering resistances for a long while, and after the taper resistance nearest the sending battery is computed, it is merely necessary to divide its resistance which, as shown in the diagram, is 17,120 ohms by .006 ampere, which gives the voltage to be applied to the line at the point where



DETERMINING SELECTOR RESISTANCES.

this bridge is connected. This voltage is 102.72.

"Assuming that the line resistance between the battery shown on the diagram is 0, then the battery voltage, of course, would be the same; however, in practice between the points where the first selector is connected to the line and the sending battery, there are retardation coils which have a resistance of about 150 ohms, so that the voltage at the battery terminals would be determined by multiplying the current flowing in the section of the line between the battery terminals and the first station, by the resistance, or 150. This would give the drop in voltage for this section of the line, and by adding this drop to the 102.72 volts, the battery voltage would be determined.

"The method outlined by Mr. Doherty works very nicely on straight circuits without branches, but on circuits where branches are connected, complications arise and in using this method for such circuits, care should be taken to assign the proper numbers to the various sections."—Editor.]

High Tension Transmission in Tennessee.—The Tennessee Power Company has been organized in Tennessee to generate and transmit 161,000 electrical horse power to Nashville and other cities in that state for light, heat and manufacturing purposes. If the three-phase system of generation and transmission is adopted, and the phases are well balanced, telegraph and telephone service in the vicinity need not suffer in consequence of the proximity of the power-carrying wires.

The K R Law as Applied to Quadruplex Working.

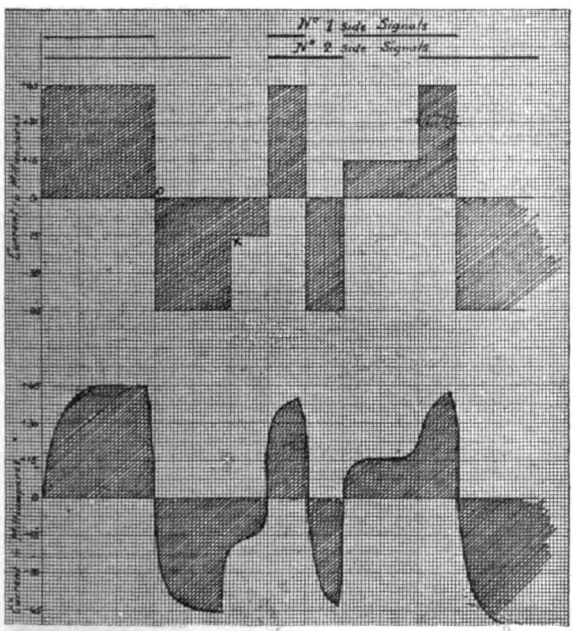
BY JOHN H. BELL, TELEGRAPH ENGINEER, WESTERN ELECTRIC COMPANY, NEW YORK.

The article on the KR law in TELEGRAPH AND TELEPHONE AGE, dated April 1, is interesting reading. From an analysis of the circuit conditions obtaining during the trial of quadruplex working between New York and Chicago, the following particulars have been deduced.

The wire resistance was 2682 ohms, and assuming that the resistance in the power leads and instrument coils added 900 ohms more, the total circuit resistance was approximately 3600 ohms. Had the insulation of the line been perfect, the 360 volts applied at Chicago would have given 100 milliamperes received current at New York. Actually, however, 57 milliamperes were received, from which it can be found, assuming the leakage to have been uniformly distributed, that the total insulation of the line was about 1200 ohms, or $1200 \times 868 = 1{,}041{,}600$ ohms per mile.

Further, it can be shown that at the sending station (Chicago) the currents were of the value of 286 milliamperes, i. e., 143 passing out to the line and 143 to the artificial line.

It will be seen, therefore, that despite the comparatively good insulation per mile, the great length of the circuit was such that, of the 143



FIGS. 1 AND 2. VALUES OF TRANSMITTED AND RECEIVED SIGNALS.

milliamperes sent out by Chicago 86 milliamperes leaked away and only 57 milliamperes were received at New York.

As Great Britain is the only country outside of America where the quadruplex system is widely used and its range of working definitely fixed, it may be of interest to your readers to learn in what respects the British system differs from the American, and some particulars of its efficiency in working. Before referring to these points, however, it will perhaps not be out of place if the theory of quadruplex working is considered in some detail.

Fig. 1 shows the perfect "square" signals which would be sent out by a perfect polechanger on an imaginary circuit having no capacity and no inductance. Fig. 2 shows the signals at the receiving instrument of an actual circuit, mutilated by capacity and inductance. The main problem in quadruplex working is to devise a means for maintaining a continuous signal at the No. 2 side relay while the polarity of the No. 1 side is changing. This particular condition is shown at o in Fig. 2, and is represented in enlarged form in Fig. 4.

Fig. 3 shows schematically the construction of the No. 2 side relay. Normally, the armature is held away from the polepiece by a spiral spring

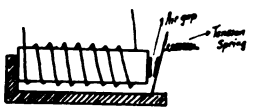


FIG. 3. CONSTRUCTION OF NO. 2 RELAY.

the tension of which is regulated so that a certain strength of current through the coil is required to attract the armature. When once attracted, however, the armature can be held over by a weaker current than is required to produce its initial movement, because the air gap in the magnetic circuit is reduced. The ratio between the "operating" and "holding" currents varies with different instruments, and with different adjustments of the same instrument. For the purposes of this paper let it be assumed that the operating current required is 30 milliamperes, and the "holding" current 20 milliamperes.

Fig. 4, curve *B O D*, shows in exaggerated form the shape of the current curve at the receiving instrument on a long line when the polarity is changing, as at *O* in Fig. 1, the armature of the No. 2 side relay meantime being required to remain attracted. If this relay be adjusted as mentioned the tension spring will pull back the armature immediately the + current drops below 20 milliamperes, and hold it till the current rises to 30 milliamperes on the — side, at which point the magnetic attraction produced by the current will again overcome the tension of the spring and the armature be attracted. This is the interval which must be bridged over by some local arrangement at the receiving apparatus: it is represented graphically by *d* (Fig. 4), and is known in professional circles as "the *B* side kick."

On a short line having small capacity the rise of the current at the receiving station is retarded to a lesser extent than in the case of a line having high capacity, and the received current may be represented by the curve *B O C*. The time interval to be bridged is then considerably shortened —as represented at *c*. If now, the insulation of this short line drops, the received current will be

Digitized by Google

reduced. It may be represented by the curve *B O E*, which is shown as reaching a maximum value of 34 milliamperes instead of 45; the interval to be bridged over being represented at *e*. Under such circumstances this interval may be reduced by slightly releasing the tension of the adjusting spring so as to allow the non-polarized relay to operate with a weaker current, say 26 milliamperes instead of the normal 30. This is shown at *F* and the reduced time interval at *f*. As the releasing of the tension spring also reduces the "holding" current required, this means for overcoming the trouble must not be pushed too far.

Otherwise the holding current will drop below the No. 1 side current with the result that the armature of the No. 2 relay will remain attracted instead of releasing on the termination of a signal as at the point *x* in Fig. 1.

It will be noticed that part of the time-interval in each case includes a period *q* which represents the time taken by the positive current in falling from the "holding" current value to zero. The current does not cease immediately the armature of the pole-changer at the sending station breaks contact, but tails off, owing to the capacity discharge from the line and the self-induction of the relays at the receiving station. It will be seen, therefore, that the self-induction and capacity assist in reducing the time interval to be bridged over, as otherwise the current would immediately drop to zero, increasing the time interval by a period *Y-q*.

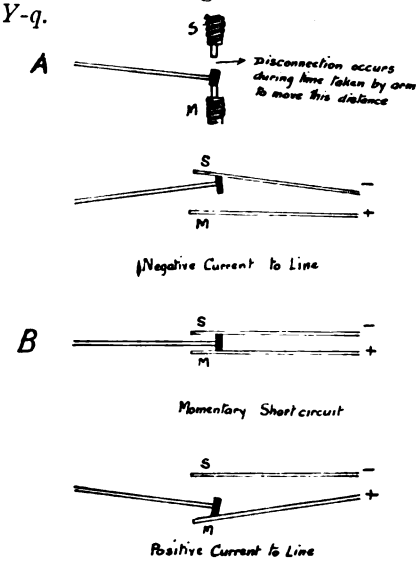

FIG. 5. FORMS OF POLE-CHANGER CONTACTS.

If now, the total time taken by the polechanger at the sending station to travel from one contact to the other is halved the moment of disconnection will occur at *N* instead of *M* (Fig. 4), and then the falling current will pass the "holding" current value at *n* instead of *m*. The time interval

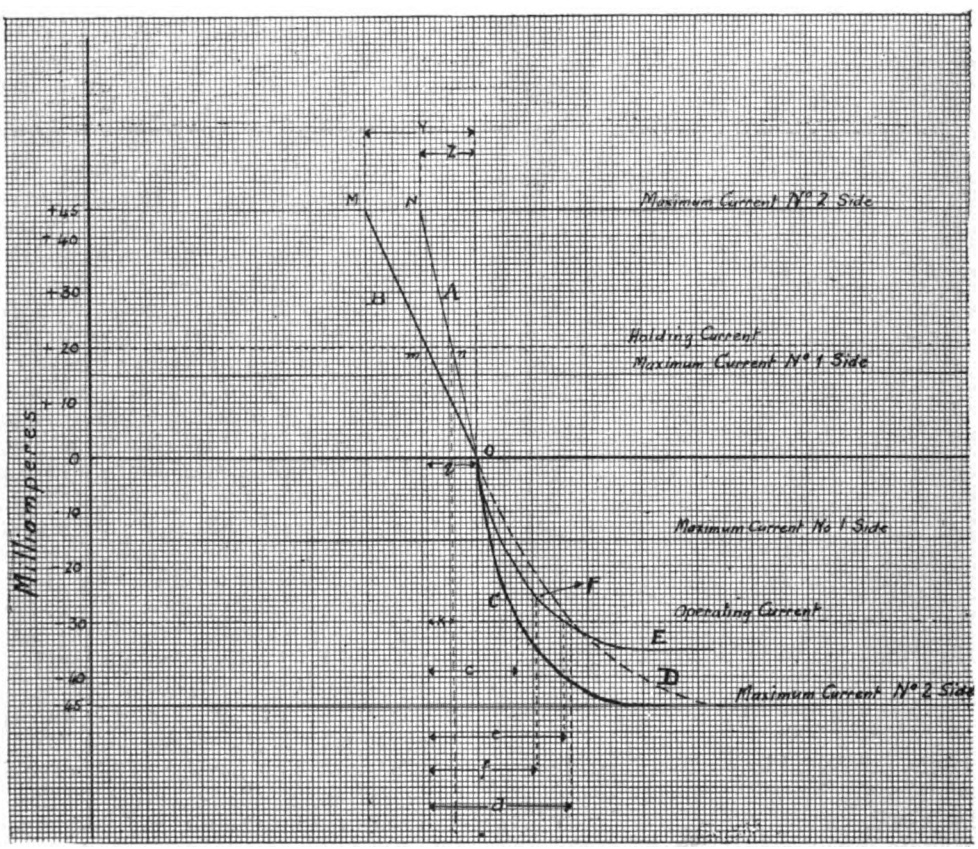

FIG. 4. CURRENT CURVES.

Digitized by Google

to be bridged over is therefore reduced by a period represented as *K*.

Various methods have been suggested to reduce this time interval and the question arises as to the comparative merits of a polechanger having a rigid armature and fixed contact points, making a total disconnection, and a polechanger having a rigid armature and spring-mounted contacts which momentarily short-circuit. Theoretical consideration of this question leads one to regard the latter as being the more efficient for two reasons:

(1) The period of no current is shorter.

(2) The balance is less disturbed.

Fig. 5 shows the contacts of the two forms of polechanger mentioned. In *A*, depicting fixed contacts, a period of no current exists during the time taken by the armature to travel from *S* to *M*. The distance of travel is made as small as possible, due care being taken that no sparking at the contact points exists. In *B*, the contacts are shown as being mounted on springs which follow up the movement of the armature so that when the latter moves from *S* to *M*, the *S* contact does not disconnect until the armature has made contact with *M*. Assuming that the same distance is observed between contact points as in *A*, it is clear that by this method the period of no current can be reduced to a very minute interval. Further, a slight rubbing of the contact points takes place and this tends to keep them clean.

The second advantage of the spring contact arrangement can perhaps best be explained with the aid of a diagram.

Assuming a potential of 150 volts at each power generator or battery (Fig. 6) necessitating a pro-

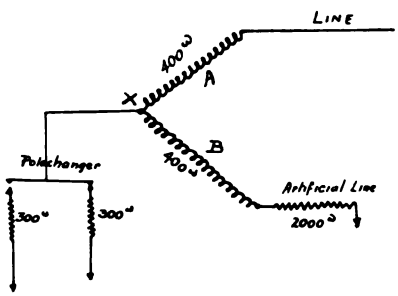

FIG. 6. DIAGRAM OF BALANCING RESISTANCES.

tective resistance of 300 ohms in each lead, and a resistance of 2000 ohms in the artificial line. At the distant office of the circuit shown in this figure the artificial line balances the line wire, the coil *A*, and the joint resistance of the two paths from *X* to ground, one being via coil *B* and the home station artificial line, the other via the polechanger and one or other of the power leads. The path via *B* is considerably greater than that via the polechanger the ratio assumed in this case being 2400 : 300, the joint resistance of which is approximately 266 ohms.

With a polechanger producing a disconnection the path through it is broken, the only path from *X* to ground being that via *B*, of 2400 ohms resistance. The balance at the distant office is therefore momentarily upset to the extent of 2400—266= 2134 ohms.

With a polechanger producing a short circuit, the path is not broken, but, instead, two paths exist, one via each power lead, giving a joint resistance of 150 ohms. The joint resistance of these paths and that via *B* then becomes approximately 141 ohms. In this case, therefore, the distant office balance is upset to the extent of 266 — 141 = 125 ohms.

When dynamos are used as generators of power, sparking is said to be more frequently experienced with a spring contact type of polechanger than with one having rigid contacts. The writer, however, has had no experience in this connection.

The spring contact type of polechanger is used in Great Britain and the correct adjustment of the contact points is regarded as of much importance. Unfortunately, however, the full advantage of this means of producing the minimum period of no current is not secured on account of the operating key being used as the polechanger. The speed of travel of the armature is thus dependent upon the operator's style of sending, and is consequently slower than if the armature were actuated by an electro-magnet, as is done in this country.

Having referred to the method employed for reducing, by apparatus design, the duration of the time interval which must be bridged over, let us now consider the construction of the bridge.

In this country the usual practice is to employ an additional coil to the No. 2 side relay, in series with a condenser, and so rectify the distorted signals at the relay. The British method is to provide a means for rectifying the signals in the local circuit, as shown in Fig. 7.

The functions of the various parts are as follows: When the relay armature is attracted there is an initial rush of current to charge the condenser, and to prevent its reaching too high a value, a 50-ohm coil is placed in the circuit. It was found that when no resistance was provided the momentary current was such as to cause welding at the contact points.

As the time taken to charge the condenser is very short, the only retarding factor being the 50-ohm coil, the flow of current through the sounder is not appreciably delayed. When the short "kick back" of the relay armature takes place the circuit conditions are exactly as repre-

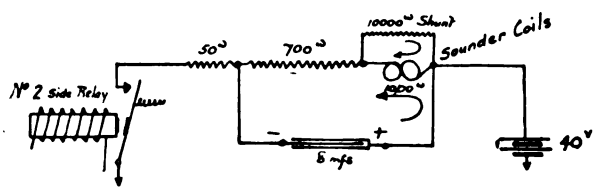

FIG. 7. METHOD OF RECTIFYING SIGNALS IN LOCAL CIRCUIT.

sented in Fig. 7. The self-induction of the sounder coils sets up a rapidly weakening current which circulates round the sounder shunt coil in the direction indicated by the smaller arrow. The

Digitized by Google

condenser discharges through the 700-ohm resistance coil and the sounder coils, as represented by the larger arrow.

A quadruplex of this design has been found to work over an artificial line of KR 84,000. On an actual underground circuit, free from inductive interference and of KR value 60,000, perfect signals have been obtained, but the margin for adjustment was small, and it was found necessary to adopt a firm style of sending on the No. 2 side.

On aerial lines, however, where varying insulation prevents a steady balance being maintained, the range of quadruplex working is much smaller and the limiting KR value must necessarily be an arbitrary one.

It can hardly be regarded as good practice to instal quadruplex apparatus on a circuit of high KR value which will work efficiently for a few days of the year only, nor is it advisable to regard quadruplex working as being impracticable on a circuit because it works inefficiently during a few days of the year when the insulation is very low. The limiting KR value should lie somewhere between these conditions. In Great Britain the figure has been placed at 30,000, and, generally speaking, an aerial quadruplex circuit of this KR will work efficiently for at least eleven months of the year.

In America the weather conditions are such as to lead one to place the limiting KR value slightly higher than in Great Britain.

When Mr. Finn's article was written the KR law was doubtless used in comparing the speech efficiency of telephone circuits, but, as probably most of your readers are aware, it has been shown that the KR law does not hold good for this purpose. Other factors besides K and R have to be considered. The efficiency of telephone circuits is now based upon comparison with a standard cable of known electrical constants.

The English-Marconi Wireless Telegraph Agreement.

Mr. Charles Bright, the well-known English authority on submarine cable matters, in commenting on the arrangement between the English postoffice department and the Marconi Wireless Telegraph Company for imperial wireless service says that although he could not understand the Government's opposition to a state-owned cable he thought the Government's contract with the Marconi Company for the establishment of an imperial wireless service sounded a good deal to its credit, inasmuch as it showed that the Government had the courage of its apparent convictions and purposed taking up and furthering an industry which was still in the making, so to speak.

"As a rule," he added, "British Governments wait till an industry has been thoroughly worked out before absorbing it, by which time the purchase price becomes abnormally high. If fairness is to be observed, it also redounds to the credit of the Government that it thinks to be before other countries in this matter. Whether it actually will be is another story. In any case, such prompt, go-ahead action on the part of the Government in regard to wireless contracts contrasts favorably with the lukewarmness in the matter of imperial cables, such as we have become accustomed to in our country for many years."

Regarding the relative value of cable or wireless, Mr. Bright said he thought that, in view of the extreme importance of the subject from national and other standpoints, a commission should be instituted to inquire fully into the whole matter.

"It would seem to me," he said, "if one method of telegraphic communication with the rest of the empire is to be regarded as a future substitute rather than as supplementary to another, that the greatest possible pains should be taken to arrive at which is the more reliable and efficient.

"One of the first subjects for investigation would be, I suppose, as to which method is being most effectively used in any particular quarter, say from the seat of war in Tripoli; or, again, which is most seriously affected by the weather and which is more vulnerable to attack.

"The Marconi system of wireless telegraphy has achieved much, and deserves hearty congratulation and support, but the Post Office does not at present seem to encourage the public use of wireless telegraphy much for transatlantic purposes, notwithstanding the apparent preference for the wireless on a larger scale."

Retirement of Mr. Weaver as Editor of the Electrical World.

Mr. William D. Weaver, for many years editor of the *Electrical World*, New York, retired from active journalistic work on May 1. On Monday, April 29, Mr. James H. McGraw, president of the McGraw Publishing Company, gave a luncheon at the Engineers' Club, New York, in honor of Mr. Weaver's retirement, at which were present all the members of the *Electrical World* staff and a few former associates and personal friends of Mr. Weaver. Several addresses were made highly complimentory to Mr. Weaver as a man and an editor, and as a token of the esteem with which he was held by his office associates, Mr. McGraw presented him with a handsome gold watch and chain, and a watch fob.

Mr. Weaver replied feelingly to the compliments paid him.

Among those who spoke were Dr. Louis Bell, of Boston, Carl Hering, of Philadelphia, and T. C. Martin, Secretary of the National Electric Light Association, of New York, all former editors of the *Electrical World*; Gano S. Dunn, President of the American Institute of Electrical Engineers, New York, and a former telegrapher; John J. Carty, chief engineer of the American Telephone and Telegraph Company, New York, and several others. There were about forty-five persons present and at the conclusion of the luncheon all joined in expressing their best wishes for Mr. Weaver's future welfare and happiness.

Trans-Atlantic Telegraphy.*

BY CHARLES BRIGHT, F.R.S.E., LONDON.

At a recent meeting which had for consideration the proposed Imperial Atlantic Cable a resolution in its favor was, for some unaccountable reason, withdrawn. If the case against the cable was so strong, it seems strange that those opposed to it should ask for the withdrawal of a resolution in its favor; still more that those in favor should—out of awe or affection—fall in with so complacent a course on such an occasion. However, no reply having been given to the speech in opposition to the resolution, the following brief observations may be made in that connection:

1. The existence of a trans-Atlantic cable monopoly *commercially* speaking has never been suggested, but our communication with Canada being now in the hands of two American companies constitutes a highly undesirable monopoly in a *national* sense.

2. A cable landed on British territory with British clerks, and *foreign ownership, directors and managers,* does not constitute British control, as anyone knows who has to do with the working of a cable system. There are several cases that might be cited to prove this. Meanwhile, the following may be quoted from an American contemporary: [TELEGRAPH AND TELEPHONE AGE, March 16]: "The eight trans-Atlantic cables of the Western Union, Anglo American, and Direct United States Companies were consolidated on March 8, under one operating management, and will be known hereafter as the *Western Union Cable System.*" Here we have evidence of the way facts are appreciated at their correct value in the United States.

As further evidence, but from *this* side, we have the following remark made by the chairman of the Anglo American Telegraph Company at its last shareholders' meeting:

"All we have to do now is to sit down and receive our dividends."

3. It is unwise to rely upon Naval supremacy as sufficient reason for allowing all our British trans-Atlantic cables to pass into American hands, especially when we remember that control of cable communication with other parts of the Empire is even more important during the period when international trouble is brewing, than during actual warfare. Germany and France have recently recognized this by establishing separate cable links to their own colonies.

4. The loss quoted on the Pacific cable as of last year was, as a matter of fact, that of some years ago—a loss which is steadily decreasing each year. Parenthetically, it may be added that we do not talk about a loss on our Navy and Army; yet efficient and reliable telegraphic communication with the rest of the Empire is equally essential, and is, indeed, *inter alia,* a necessary strategic adjunct.

5. As an argument against the proposed Imperial Atlantic Cable, it was stated that the line would require to be laid in duplicate. Personally, I should propose that the duplication should be effected by "wireless," either with the existing Marconi system or by establishing a new wireless system on an extreme northern route. But, in any case, it may be pointed out that, whereas a cable on the route of the "All British" Pacific Cable would be far more likely to give trouble than one across the Atlantic, the Pacific line has only once been interrupted—and that quite recently—for a very brief period, on one of the shorter sections. It has, in fact, got on very well by itself ever since it was laid, some twelve years ago. On the other hand, its value as a strategic asset was more or less wiped out on the day when its Atlantic connecting links became entirely American.

6. A great deal was said about the government wireless scheme; but though much was made of the cost of the proposed Imperial Atlantic Cable, there was no reference to the corresponding cost of the wireless project, a cost which has been already estimated at a figure considerably in excess of that which would be entailed by the Atlantic cable link.

7. A point was made that all the new wireless stations were to be on British territory. But this by itself does not appear to be of transcendent value in the case of wireless, unless the intervening ether space can be also rendered "All-British."

8. Apparently the principal opponent to the Imperial Atlantic Cable was greatly impressed with the efficiency of "Wireless;" for he spoke of the cable system as being conceivably "knocked out" by wireless. Suggestions of this sort, unfortunately have their effect when coming from certain quarters, even though based on no direct technical knowledge of the two methods of telegraphy. Thus, holders of cable stock are being needlessly disturbed, partly on this account and partly due to the constant "writing up"—very much "up"—in the non-technical press of everything to do with wireless telegraphy, without any corresponding announcement as to what is being done by cables in the ordinary every-day course.

9. Special attention was called to "a new automatic method by which messages would be ticked off at the rate of 50 words a minute." Apparently this had reference to the Imperial wireless scheme; and if this be so superior—as seemed to be thought—why trouble about cable rates? It was also stated that each station was to work "practically instantaneously," yet each was to "repeat to the other"; most of us know something of those repetitions, while we also know of the great value (and the reverse) of simultaneously spreading news and information to a wide and attentive audience—whether for legitimate press purposes or otherwise. In the case of war it would be distinctly "otherwise."

The present position certainly suggests the desirability of full and important public inquiry into the relative merits of cable and wireless telegraphy—as I have constantly urged for. The two systems should, in fact, be put to actual test by independent parties under similar conditions. That would be better than mere generalizations such as seem so rife just now.

Electrical Review, London.

Testing on Railroad Telephone Circuits.

(*Continued from page 276, May 1.*)

BY K. W. ENDRES, NEW YORK.

BATTERY TROUBLE.

If there is no thump on the line when the dispatcher is calling a way-station, and he is unable to ring the station bells, the sending battery circuit is open. The dispatcher should look into the battery cabinet and see if the fuse, which is placed in the battery circuit, is blown. This can easily be replaced. If not, he should examine the sending relay to see if the contacts are made firmly.

RELAY OR KEY TROUBLE.

If the sending relay does not operate, there is an open in the local circuit, or trouble in the sending key. It should be tried with another key or with the strap key. This will place the trouble. Then examine the connections of the eight cell battery which operates the relay. This is wired to the line binding posts on the relay. If the trouble is in the sending key and cannot easily be located by inspection, or fixed, this key should be taken out and replaced by a spare key which can be adjusted for the station desired, or else the particular station whose key is gone may be called by means of the strap key, temporarily.

TELEPHONE SET TROUBLES.

If able to signal way-stations, but unable to talk or hear, the dispatcher's telephone cord may be broken at the plug or the fuses may be blown at the protector which is wired in his telephone set leads.

A heavy, scratching noise while the dispatcher is calling a station would be caused by a ground on the line, condensers broken down in his telephone set, or the condensers which are bridged across the retardation coils to eliminate noise, broken down. The latter would be noted by an exceedingly loud "click" in the receiver as the contacts are made in the sending key.

If the dispatcher's talking battery circuit is open, he will not obtain any "click" by opening and closing the switching key in his transmitter circuit.

If the induction coil in the dispatcher's desk set box is open, the grade of transmission both for talking and receiving will be very faint indeed, if he is not totally unable to talk or hear. If the dispatcher is equipped with a hand generator for calling siding and portable telephones, and this should become bridged across the circuit by accident, it will act in exactly the same way as a short circuit between the dispatcher's office and the first way-station, and he will be unable to signal any stations on his line.

WAY-STATION TROUBLES.

Following is a list of some of the possible troubles which may occur at a way-station to prevent the selector bell at that point from ringing.

1. In case selector sets using local battery-ringing are employed, the local battery bell circuit at the stations may be open, or the batteries may be exhausted and need replacing. A pocket battery gauge may be used for testing this battery.

2. While the bell and selector box are nearly dust-proof, the bell contacts at the way-station may, if the set is located in a very dusty place, become dirty and prevent the bell from ringing.

3. The contact on the selector at the way-station which controls the bell may, after long continued use, become dirty in extreme cases. The chance of this, however, is very remote since the contacts are of platinum and the selector is hermetically sealed. The selector can be tested for this trouble by short circuiting the local circuit binding posts upon the selector. If the bell rings in this case, it is an indication of trouble in the selector contact. If it does not ring, it is an indication of trouble in the bell battery or in the bell itself.

4. The answer-back signal may not be received. This indicates either that the bell does not ring, or if it does ring, the front contact on the armature of the bell is not making properly, or that the answering-back circuit at the way-station is open.

WAY-STATION CANNOT TALK NOR HEAR.

One advantage of a telephone circuit is that if anything is the matter with the line, a way-station telephone set, or the dispatcher's equipment, it will generally betray itself in some way when an attempt is made to talk. It may be that there is noise; possibly the operator cannot talk nor hear. Again, he may be able to talk and not hear and vice versa. The matter of noise has already been covered. It is usually due to line trouble.

If the way-station can neither talk nor hear, a receiver should be bridged across the line terminals where they enter the building. This will indicate whether the trouble is inside or not. Conversation will be heard if there is no trouble outside. Having found the trouble to be inside, the circuit should be carefully gone over to see that it is correctly wired and that there are no open or loose connections nor short circuits. Test the induction coil for continuity in both the primary and secondary windings. Test the condenser to see if it is crossed. Finally, try a new transmitter and receiver after testing their cords for continuity.

TRANSMITTER TROUBLE.

In case trouble is found in a transmitter, it may be found to be "packed"; in other words, the granular carbon inside of it, which transmits speech through the variation of its resistance caused by the movement set up by the voice may become jammed together in a solid mass and have no motion under the action of the voice vibrations. This can be remedied by loosening the button on the face of the transmitter diaphragm and shaking or tapping the instrument, then tightening the button.

RECEIVER TROUBLE.

Receiver trouble is liable to be either an open circuit of the windings which can be easily found, or weak magnets. These latter can be noticed by observing the strength of the pull on the diaphragm as compared to that on a receiver in

Digitized by Google

good order. Rough treatment of a receiver, such as dropping it, will sometimes cause this demagnetization.

WAY-STATION CANNOT TALK.

Inability of a way-station to talk, while still able to hear perfectly, is likely to be caused by an open circuit in the secondary of the induction coil (in desk set box). No side tone will be obtained in this case.

WAY-STATION SWITCHING KEYS.

Care should be taken when installing, as well as when locating trouble, to see that the switching keys at the way-stations are all operating as they should, and that there are no crosses between the springs. This key is the one used by the way-station operator when he talks on the circuit, and which he releases when he listens. A drop of solder or a bit of wire carelessly thrown away will often cause just such trouble as this, and the telephone set is very likely to be found open or crossed in the springs of this key.

TESTING CONDENSERS AND RESISTANCES.

All condensers and resistances installed around relay contacts and across retardation coils, as well as in desk set boxes, should be tested to see if they are in good condition. In testing a condenser, connect five or six cells of battery through a milliameter or a buzzer to its terminals. If there is no reading nor any sound, the condenser is not short circuited. Then connect the condenser in series with a hand generator and the bell. Operate the generator, and if the bell rings, the condenser is all right and not open.

A resistance coil is tested for continuity of its circuit by placing it in series with a battery and buzzer or ammeter.

PRIVATE RAILROAD TELEPHONE CIRCUITS.

In addition to the telephone train dispatching circuits which are being rapidly spread over the railroads at the present time, on all the large systems at any rate, there also exists a class of telephone lines which differs in no respect from the ordinary commercial local and long distance circuits, except that they are used by the railroad companies. These lines may have circuits extending hundreds of miles between the various division headquarters, in which case they are exactly similar to the commercial long distance lines, or they may be short local lines running from different private branch exchanges in the various office buildings of the railroad company. In both cases, however, provision must be made for testing these lines and maintaining them in first class condition.

Means of doing this are exactly the same as are employed in regular telephone offices. The elaborate and complicated wire chief's desk is not, however, required in these cases, owing to the fact that there are hardly ever a sufficient number of lines on an equipment of this character to warrant it. Condensed wire chief's desks, therefore, have been brought out by the Western Electric Company (one of which is described herewith), that afford means for accurately testing for practically all troubles common to both magneto and central battery exchanges. The application of such a testing cabinet is universal. It can be arranged for mounting either alongside of the switchboard or in the terminal wires, or in the terminal room.

Tests can be made a very simple matter without complicated mathematical calculations for grounds, short circuits, opens, bad joints, and in fact practically all troubles common to exchanges.

TESTING BATTERY.

A sufficient number of dry cells, usually about twenty-four, connected in series to give thirty volts is required for the testing battery (Fig. 11). Great care should be taken that the testing battery maintains a constant voltage, otherwise the voltmeter calculations will not be dependable. The voltage of the testing battery may be measured by having a vacant jack on the switchboard short circuited (in other words, the "tip" and "ring" connected together). By plugging into this jack and operating the key *V* (Fig. 12), the voltage of the testing battery will be indicated upon the voltmeter. If the voltage is lower than thirty, it may be increased by connecting one or more dry cells in the series; if the voltage is higher than thirty, it may be reduced by removing one or more cells from the series.

FIG. 11. TESTING CABINET.

The condition of the testing batteries should always be tested by plugging the test cord into the special jack and operating the keys *V* and *VS*. If the operation of the key *VS* causes the needle to fall back more than four or five points, or if the needle begins to move back gradually after the keys have been left operated for a few seconds, the testing battery is too far exhausted to give readings which may be considered dependable.

The testing batteries may be located in the terminal room and wiring therefrom connected to the testing cabinet. Not more than thirty feet of No. 20 B. & S. gauge copper wire should be used for this connection. If it is absolutely necessary to locate the batteries at a greater distance from

the testing cabinet, correspondingly larger sized wires should be used.

The lead, or wire, from the zinc side or negative pole of the dry cell is to be connected to the terminal marked "—30V", meaning the negative side of the 30-volt battery.

The lead from the carbon, or positive side of the dry cell is to be connected to the terminal marked "+30V," meaning the positive side of the 30-volt battery.

(*To be continued.*)

Sulphated Storage Cells.

"The Regeneration of Sulphated Storage Cells," was the subject of a paper presented by Messrs. C. W. Bennett and D. S. Cole before the recent meeting in Boston of the American Electrochemical Society.

The method of regeneration recommended was to produce sodium hydroxide in the sulphated grid. This is done by electrolysis with sodium sulphate as electrolyte, the current being sent through the cell in the direction of charging. Sodium hydroxide is then formed in the pores of the lead plate and sulphuric acid at the lead-dioxide plate. The results obtained were remarkably good. The concentration of sodium sulphate recommended is 200 grams of the crystallized salt per liter. It should be chemically pure. After treatment the plates need not be thoroughly washed, but dipping in water is sufficient. The time of charging for the worst cells was about sixty hours at the eight-hour rate. The method was tried upon a battery of fifty-two cells which had been improperly handled and were in bad condition. Before the treatment the energy efficiency was found to be 42.5 per cent. and the capacity was only half of the rated capacity. After treatment the energy efficiency was found to be 81.1 per cent., the energy capacity was 88.7 per cent. of rated capacity and the ampere-hour capacity 96.9 per cent. of rated capacity. This battery had a capacity of 7.5 amperes and the cost was about 20 cents per cell. The gain in efficiency would pay for the treatment after ninety charges and discharges, providing energy cost five cents per kilowatt-hour.

Telegraphs and Telephones on Panama Canal.—The United States Government now has forty copper telephone and telegraph lines across the isthmus of Panama from the Atlantic to the Pacific. The first lines used by the Government were constructed of iron wires. Ants made the use of wooden poles impractical along the canal. The present line is constructed of old steel rails left by the French after their canal work. There are 1400 telephones in use and seven exchanges. There are thirty American female operators, most of them the daughters of canal employes. The canal work is all directed by telephones. Mr. A. B. Kratz is superintendent of telephones and telegraphs for the Panama Canal.

TELEGRAPH AND TELEPHONE AGE is the leading paper in these two fields and is progressive and newsy. Subscription price, $2 00 per year.

Telephone Pioneers of America.

F. E. KINSMAN.

Mr. Frank E. Kinsman, of North Leominster, Mass., of which place he is a native, is one of the first telephone pioneers in point of early connection with the industry, having taken up the work in the fall of 1876. He was at that time engaged in the development of an express cable system in Boston, Mass. The device meant instantaneous communication, something on the plan of the district telegraph service which about that time was introduced in Boston, but involved a far more complicated apparatus. It was while engaged upon this work that he first heard of the telephone as exhibited at the Centennial Exposition. As a result of an acquaintance very close to Mr. Alexander Graham Bell, and others interested, Mr. Kinsman was shown a telephone which he believes was the one exhibited in Philadlphia, or the one following it. As soon as

F. E. KINSMAN,
Retired, Leominster, Mass. (1876).

possible thereafter he got into communication with Mr. Sanders, who referred him to Mr. Gardner G. Hubbard as the business man of the affair. Mr. Kinsman succeeded in getting Mr. Sears to subscribe $15,000 for a one-third interest. Mr. Kinsman was to have a third and the remainder was to be used for future promotion purposes, but circumstances finally prevented the consummation of the deal with Mr. Hubbard for the exclusive use of the telephone for what has since been denominated central office purposes. He then engaged with Mr. E. T. Holmes of the Holmes Burglar Alarm Company of Boston to enter his employ for the purpose of assisting in the establishment of a telephone express call central office system. The first line was built from Tremont Street near Boylston over the housetops to the Holmes Burglar Alarm office on Washington Street, near the corner of Milk Street. Mr. Kinsman remained with Mr. Holmes until the fall of 1877 when he went to New York and from there to Chicago, where he took what is believed to have been the first telephone subscription west of the Alleghany mountains. Mr. George Sturges, president of the Northwestern National Bank was the subscriber.

After his experience in Chicago, Mr. Kinsman spent some months in Ohio with Mr. Frank G. Beach, establishing exchanges in different localities, after which he returned to New York as manager of the Fourteenth Street, the Williams Street and the Whitehall Street central offices. Following this, he was made superintendent of repairs and attachments and was succeeded by Mr. John A. Seely, who in turn was succeeded by Mr. J. J. Carty, now chief engineer of the American Telephone and Telgraph Company, New York. Mr. Kinsman resigned his telephone position August 1, 1881, to go into construction business on his own account.

During the subsequent business career Mr. Kinsman was prominently identified with the early work in the electric light industry and he is the inventor of several devices, the most notable being the automatic train stop which is now used in the New York and Boston subways and underground railroad tunnels.

Mr. Kinsman retired from active business four years ago, but still keeps up his interest in the telephone and other electrical improvements.

Press Rates in Canada.

The Board of Railway Commissioners of Canada heard a complaint from the Canadian Press Limited at Toronto on Wednesday, May 1. The complaint was a request that the Great North Western Telegraph Company and the Western Union Telegraph Company charge the same rates for Associated Press service in New Brunswick and Nova Scotia as does the Canadian Pacific Railway.

The second item of the complaint asked that the rate for newspaper day-specials between points in New Brunswick and Nova Scotia be reduced from ½c. per word to ¼c. per word, the same as charged between points in Ontario and Quebec. The Board of Railway Commissioners practically ruled out the first item of the complaint and has taken the second item under consideration.

The Great North Western Telegraph Company was represented by its general manager, Mr. G. D. Perry, Toronto; the Canadian Pacific Railway Company's Telegraph by Mr. W. J. Camp, assistant manager of telegraphs, Montreal, Que., and the press was represented by Mr. McCreedy of St. John.

The Board of Railway Commissioners was represented by Mr. D'Arcey Scott, Dr. Mills and Mr. Maclain. The chief commissioner, Judge Mabec, was not present, having been operated on for appendicitis the day previous.

The Railroad.

Mr. Charles Selden, superintendent of telegraph of the Baltimore and Ohio Railroad Company, Baltimore, Md., was a recent New York visitor, as was also Mr. W. J. Camp, assistant manager of telegraphs, Canadian Pacific Railway, Montreal, Que. Mr. Camp was accompanied by Mrs. Camp, and both attended the ceremonies at the unveiling of the telegraph monument at Harriman, N. Y., May 2.

Mr. Joseph P. Church, chief clerk to the superintendent of telegraph, Wabash Railroad, Decatur, Ill., has been appointed acting superintendent of telegraph of that road, vice G. C. Kinsman, resigned. Mr. Kinsman will hereafter reside on the Pacific Coast.

Mr. Carl R. Gray, president of the Spokane, Portland and Seattle Railway, and who is to become president of the Great Northern Railway, began his railway career as a telegrapher in 1882 on the St. Louis and San Francisco Railway. He was born in 1867.

Convention of Association of Railway Telegraph Superintendents.

The topics committee of the Association of Railway Telegraph Superintendents announces the following papers to be read at the annual convention to be held in New York, June 4:

"Maintenance Standards and Methods," by G. M. Yorke, engineer, Western Union Telegraph Co., New York; "Possibilities of High Speed and Automatic Telegraph Systems in Railroad Service," by W. N. Fashbaugh, traffic engineer, Western Union Telegraph Company, New York; "The Handling of Supplies," by W. G. Higgins, superintendent supplies, Western Union Telegraph Company, New York; "Construction Standards and Methods," by R. E. Chetwood, engineer of construction, Western Union Telegraph Company, New York; "What the Telephone Has Done for the Santa Fe Railway," by L. M. Jones, superintendent telegraph, Atchison, Topeka & Santa Fe Railway, Topeka, Kan.; "The Use of the Main Line Relay in Telephone Selector Operation," by W. W. Ryder, general superintendent of telegraph, New York Central Lines, Chicago, Ill.

A meeting of the entertainment committee was held May 8 in the directors' room of the Thomas A. Edison Company, Inc., West Orange, N. J., and discussed the programme. (See TELEGRAPH AND TELEPHONE AGE, April 16 and May 1, for details of programme). Mr. Edison was present and promised to accompany the party to the clam-bake to be given at Travers' Island by Mr. Belvidere Brooks in behalf of the Western Union Telegraph Company, Friday, June 7, after the entertainment at the Edison works and Country Club luncheon in the afternoon at West Orange. The following members of the Committee were present at the meeting, besides Mr. Edison: L. S. Wells, L. B. Foley, W. E. Harkness, A. D. Walters, A. P. Eckert, E. E. Hudson and R. A. Patterson.

The headquarters of the Association will be at the Waldorf-Astoria hotel and the meetings will be held at the same place.

The rates for accommodations at the Waldorf-Astoria are as follows:

Two dollars per day for single room without bath for one person, with bath, $3.00 up.

Double rooms for two persons, without bath, $4.00 per day up, with bath, $5.00 up.

Two double rooms, with bath, for four persons, from $8.00 up, for the two rooms, or $4.00 per room.

Following is the programme:

On Monday, June 3, an informal reception will be held at the Waldorf at 8:30 p. m.

On Tuesday, June 4, there will be business meetings morning and afternoon, and the ladies will be taken on a sight-seeing tour in automobiles in the afternoon. At night there will be a theatre party, as already announced.

On Wednesday there will be a shopping tour for the ladies in the morning and in the afternoon the men will make a visit of inspection to the Western Union Telegraph Company's headquarters, and the New York Telephone Company's Cortlandt Street Exchange, and at 5 p. m. the entire party will take a trip to Coney Island by steamboat.

On Thursday there will be business sessions morning and afternoon and the ladies will be taken on a trip around Manhattan Island by boat. In the evening the entire party will attend a roof-garden entertainment.

On Friday a visit will be made to the Edison works, at West Orange, N. J., and after luncheon at the Country Club at West Orange, as the guests of Mr. Edison, the party will return to New York over the Erie Railroad and land at West Twenty-third Street, where they will take automobiles for the Country Club, Travers Island. At Travers Island, the party will be entertained at a clambake given by Mr. Belvidere Brooks, in behalf of the Western Union Telegraph Company.

Mr. P. W. Drew, superintendent of telegraph, Minneapolis, St. Paul & Sault Ste. Marie Railroad, Chicago, Ill., will be glad to furnish any other information regarding the convention.

Telephone Dispatching on Birmingham and Southeastern Railway.—The Birmingham and Southeastern Railway Company has placed an order with the Western Electric Company for the apparatus necessary to equip ten way-stations with selective signalling apparatus. The telephone circuit is to be of No. 14 B. & S. gauge copper wire, and will be approximately forty-six miles in length, extending from Union Springs to Eclectic, Ala. The train dispatcher will be located at Union Springs.

Telephone Dispatching Equipment on East Carolina Railway.—The East Carolina Railway Company has placed an order with the Western Electric Company for telephone train-dispatching equipment. Ten way-stations are to be equipped with selective signalling apparatus. A large

Digitized by Google

quantity of miscellaneous material is also to be furnished. The telephone circuit will be about forty miles in length, extending from Tarboro to Hookerton, N. C. The dispatcher will be located at Hookerton.

Municipal Electricians.

Electrical Engineer New York Fire Alarm Bureau.—Mr. Leonard Day has been appointed electrical engineer in charge of the Fire Alarm Telegraph Bureau, New York, vice John C. Rennard, resigned.

Convention of Municipal Electricians.—The mayor of Peoria, Ill., in which city the seventeenth annual convention of the International Association of Municipal Electricians will be held August 26-30, will deliver the opening address on the evening of August 26 at the Jefferson Hotel, which will be the Association's headquarters. Ample room will be provided at the hotel for the exhibition of apparatus and appliances. Mr. W. E. Walgamott, city electrician, Peoria, Ill., will be glad to give further information regarding exhibit space. Mr. Clarence R. George, city electrician, Houston, Tex., is secretary of the Association.

The Telephone.

New England Telephone Directors.—Thomas B. Bailey and Charles H. Wilson have been elected directors of the New England Telephone and Telegraph Company, to succeed John F. Hill and F. D. Proctor.

Injunction to Restrain Telephone Merger.—Application has been filed in the Superior Court in San Francisco, Cal., for an injunction restraining the Pacific Telephone and Telegraph Company from operating or conducting the plant of the Home Telephone Company in the city and county of San Francisco, and to prevent the merger consummated March 15.

New England Telephone Company's Report.—The New England Telephone and Telegraph Company, in its report for 1911, shows gross earnings of $13,849,394, an increase of $677,686 over 1910. Net earnings were $2,995,487, equivalent to 7.64 per cent. on the capital stock, compared to 8.15 earned on the same stock last year. The surplus for the year was $350,965, a decrease of $492,343.

Long Distance Telephone Charges by the Mile.—Application has been made by the Pacific Telephone & Telegraph Company to the California state railroad commission for permission to charge long distance telephone rates by the mile. With the commission's consent, it will establish a rate of half a cent per air-line mile, with an additional five cent terminal charge for a one-minute conversation.

Telephony in Italy.—The Italian Telegraph and Telephone Department has commissioned the Bell Telephone Manufacturing Company of Antwerp, to extend the telephone exchange at Rome, equipped by that firm some years ago. Since the taking over of the telephone service by the State, the Bell Company has equipped not only the exchange at Rome, but those at Milan, Naples, Catania, Genoa and Turin.

Telegraph and Telephone in Straits Settlements.—In the Straits Settlements there are now 218 miles of telegraph and 7,321 miles of telephone wire. The Oriental Telephone and Electric Company (Ltd.) operates in Singapore, and the Government elsewhere. The 2,018 miles of telegraph and 3,118 miles of telephone wire in the Federated Malay States are all Government owned.

Deaths of Telephone Pioneers.—Secretary Henry W. Pope of the Telephone Pioneers of America has issued memorial leaflets of five telephone pioneers who have died since the first of the year, as follows: W. S. Chapman (1879), at Chicago, February 5; C. A. Nichols (1879) at Springfield, Mass., March 29; J. W. Wilson (1885), at Oklahoma City, Okla., March 30; F. C. Simpson (1890), at Kansas City, Mo., April 6; G. H. Hubbard (1889), at Jersey City, N. J., April 10.

Telegraph and Telephone Employes in London.—According to a recent official statement, the London Central Telegraph Office employs 4,456 persons, and the London Telephone Service 1,796. The former includes thirteen superintendents, 112 assistant superintendents, and 158 overseers, with 1,632 telegraphers, and 387 members of the cable-room staff. The latter comprises twelve exchange managers, and a female staff consisting of one superintendent, three supervisors, 160 assistant supervisors, and 1,402 telephonists.

Decision Affecting Extension Telephones.—A citizen of Granville, N. Y., complained to the Public Service Commission that the New York and Vermont Home Telephone Company made an excessive charge for an extension telephone, and asked the Commission to issue an order permitting him to install in his office and home at his own expense an extension telephone and have the same connected with the telephone system of the company and that he be permitted to use this extension telephone without any charge on the part of the company. In the order made by the Commission it is recited that if it were to grant the relief asked for by this complainant, it would necessarily throughout its entire jurisdiction have to permit the unlimited connection of extension telephones by subscribers to the service without charge and without control of the character of instruments connected or their maintenance by the telephone company. This practice, the Commission says, would be so obviously improper that it cannot be sanctioned by the Commission.

Associated Press.

Mr. Frank H. Trickle has been appointed traffic chief in the Eastern Division of the Associated Press, with headquarters in New York.

TIME
IS THE
CHIEF COMMODITY

The amount of cash paid for labor and for **service on a time basis** exceeds that paid for all other articles of merchandise in the markets of the world.

And yet, there is no other item of commerce so carelessly weighed or measured.
Also there is no other article of value so recklessly wasted as is time.

WHEN THE TIME OF A TELEPHONE TOLL LINE IS WASTED

the loss in revenue to its owners is more direct and greater in amount than a similar waste in other industries. It is, therefore, of the utmost importance that the time of use of toll circuits be accurately measured.

THE CALCULAGRAPH

is the only practicable instrument for timing telephone tol messages.
Without brain assistance, it subtracts the time of commencing a conversation from the time of ending and prints the difference — the elapsed time of the use of the circuit.
It makes no clerical errors and insures pay for all "excess minutes."

EDISON BSCO PRIMARY BATTERY

The Standard Closed Circuit Cell

As a chain is no stronger than its weakest link, a telephone train despatching system is no more reliable than its most inefficient station.

Railroad accidents are not respectors of locality. They are as liable to occur in remote districts as on the more accessible parts of the road. It behooves the Telegraph Department, therefore, to fit each station for heavy, continuous service.

A transmitter cannot be expected to render its best service if the source of current which actuates it is not capable of maintaining uniform voltage so necessary for distinct transmission, under constant service.

All open circuit types of primary battery (dry cells coming under this classification), quickly polarize when discharged continuously at even a moderate rate, with a consequent drop in voltage. This weakening of the magnetic field in the transmitter naturally impairs the transmission.

It isself-evident that, unless a transmitter is supplied with a dependable source of current, the telephone system is liable to fail at the weak link, just at the time when highest efficiency is required.

If you stop to consider that the most highly developed type of closed circuit primary battery, the Edison BSCO is also the most economical in service, it is apparent that no good reason exists for taking a chance with a battery not fitted for the requirements, and thus running the risk of failure, under trying circumstances, of a carefully designed and constructed system.

The Edison BSCO cell is the latest Primary Battery development of the Edison Laboratories. It is the ideal battery for telephone talking circuits, on account of its long life, uniform voltage and low internal resistance.

The cheapest form of Primary Battery energy

The London Radio-Telegraph Conference.

Prof. Willis L. Moore, chief of the United States Weather Bureau, Washington, D. C., will represent the Department of Agriculture at the Radio-Telegraph Convention in London, June 4. As previously announced, the United States Navy will be represented at the convention by Rear-Admiral John R. Edwards, U. S. N., head of the American delegation. Lieutenant-Commander David W. Todd, U. S. N., and Mr. Louis W. Austin, Ph. D. The delegates appointed to represent the Department of Commerce and Labor are John I. Waterbury, of New York; Dr. Arthur D. Webster, of Clark University, Massachusetts; John Hays Hammond, Jr., and William D. Terrell, of New York. The War Department will be represented by Major George O. Squier, Major Edgar Russell and Major Charles McK. Saltzman.

The United States delegation to the London Radio-telegraph conference held a tentative meeting in Washington May 3. This meeting will be followed by others for the purpose of outlining a programme for the work at London. It is stated that one of the propositions to be submitted before the conference by the American delegates will be to lengthen the radio wave for distress communications so as to avoid confusion.

Mr. W. D. Terrell, one of the American delegates to the London Radio-Telegraph conference, is an old-time telegrapher and has occupied many positions of prominence in and out of the telegraph service. He was born in Golansville, Va., August 10, 1871, and entered the telegraph service in that place in 1889 as manager for the Postal Telegraph and Cable Company, afterwards becoming manager at Alexandria, Va. Later he went to Washington for the same company as operator, where he was promoted to the positions of traffic chief and wire chief successively. His next change was to the position of manager of the telegraph and telephone department of the American Can Company, New York. Later he was placed in charge of the telegraph department at the New York Custom House, and since July 1, 1911, he has filled the position of U. S. Wireless Ship Inspector for the Department of Commerce and Labor, North Atlantic District, which extends from New York to the Canadian boundary.

T. M. B. A. Assessment.—Assessment No. 537 has been levied by the Telegraphers' Mutual Benefit Association to meet the claims arising from the deaths of W. H. Campbell at New York, J. Egan at Winnipeg, Man., C. W. Henderson at Dorchester, Mass., C. E. Case at Norwich, Conn., and C. M. Cunningham, at Brooklyn, N. Y.

An Old Telegraph Key.—Mr. George C. Wood, of the Western Union office at Gloversville, N. Y., possesses a telegraph key which it is stated was designed by Prof. S. F. B. Morse in 1845. It came into Mr. Wood's possession in 1848.

Dinner of the "Dot-and-Dash" Club.

The first dinner of the "Dot-and-Dash Club," of Philadelphia, Pa., was held at Kuegler's, May 11, and was a highly enjoyable and successful affair. Fifty-six persons sat down to the horse-shoe-shaped table at seven o'clock, including invited guests who came from New York and near-by cities. Mr. James Merrihew and Mr. Ashton G. Saylor, general superintendent of the Western Union Telegraph Company, New York, came over from New York in their automobiles. Mr. S. S. Garwood, president of the club presided.

It was "Reminiscent Night," and some of the old-time stories told were revelations to some of the younger set. Col. Joseph S. Green carried off the honors as being the oldest operator in the service having begun November 11, 1846. A stand of handsome roses was presented to him by the club and he was heartily cheered.

Resolutions of regret at the absence of Mr. J. B. Taltavall, Mr. W. T. Westbrook and Mr. D. H. Bates were adopted by a standing vote. Mr. C. B. Wood made a humorous speech and was unmercifully ridiculed somewhat after the fashion of the Clover and Gridiron clubs, but the more he was interrupted the wittier he got and retorted upon his annoyers with telling effect. Mr. I. D. Maize gave a history of the Philadelphia bible and stated that in a week it would be placed in the operating room as the property of the Philadelphia office.

A letter, dated 1846, from Amos Kendall was read making appointments of operators; also one from James D. Reid, of an early date, and action was taken to co-operate in the Reid memorial project.

Mr. A. G. Saylor made an excellent address, his subject being mainly on the friendly feelings he still held for "Slow Old Philadelphia." Messrs. C. E. Bagley, F. H. Griffin, Harvey Williams, F. E. Maize and W. S. Burleugh, also made addresses.

Mr. C. P. Bruch, president of the Magnetic Club, New York, made some complimentary remarks about the Dot-and-Dash Club, and was heartily cheered.

Those present were Messrs. James Merrihew, C. P. Bruch and A. G. Saylor, of New York; S. S. Garwood, F. W. Griffin, C. E. Bagley, J. H. Wilson, Robert C. Mecready, C. W. Wendel, R. A. Barton, H. A. McCanna, E. W. Miller, C. E. Diehl, J. A. McNichol, A. W. Ford, W. M. Fitzgerald, G. M. Foote, A. E. Zintl, A. C. Bagley, R. L. Massey, W. P. Bowers, M. N. Redding, A. G. Strickland, R. P. Atkinson, Edw. L. Fitzgerald, Morris Ruberg, E. H. Locke, Robert C. Murray, R. C. Bartley, W. W. Anderson, Dan'l P. Carlin, Jos. MacIver, Ed. J. Smith, G. O. H. Bentz, R. A. Black, David R. Mitchell, Henry C. Leahy, Edwin C. Boileau, John A. Maguire, W. W. Donnelly, A. G. Wallace, E. H. Shriner, J. S. W. Phillips, C. W. Zecker, Edmund H. Zinser, John A. Shea, Harry M. Hughes, Clement H. Congdon, Leo D. Firman, Harvey Williams, Frank E. Maize, I. D. Maize, Andrew S. Weir,

C. B. Wood, John A. Chapman and John V. Berger.

Entertaining Chicago Night Messengers.

On the afternoon of April 16 about 100 members of the night messenger force of the Western Union Telegraph Company at Chicago were entertained by the Y. M. C. A. and the telegraph company in that city. There was an indoor baseball game between the main and branch office messengers, which was quite exciting and resulted in a score of 8 to 7 in favor of the main office team; after which there were relay races followed by the tug-of-war, in which all the boys participated. A substantial supper was provided for the boys by the company at the close of the games, and several of the officials of the telegraph company and of the Y. M. C. A. showed their interest in the affair by attending in person.

The entertainment was keenly enjoyed by all. Night captain of the messengers, William J. Holland, in letters to John Fitzpatrick, district commercial superintendent, M. J. Tully, chief of the delivery department and H. L. Lindstrom, manager of messengers, expressed the appreciation of his boys for the entertainment.

The company and the Y. M. C. A. entertained the day messengers in a similar manner December 18, 1911, but because the night boys could not attend, the entertainment of April 16 was provided for them.

Washington Western Union Note.—Mr. J. W. Collins, former general traffic chief of this office, who was recently appointed assistant plant superintendent at Philadelphia, Pa., was presented with a handsome diamond ring by the operating force on his departure to take up his new duties. The presentation was made by Mr. Joseph D. Steele, wire chief.

Notes from Western Union Headquarters, New York.

Mr. W. A. Young, formerly manager at Lakewood, N. J., has been attached to the office of district traffic superintendent Herbert Smith, New York.

Mrs. M. M. King, nee McLaren, formerly of this department, died in Brooklyn, April 28. Her remains were buried at Flushing, N. Y.

W. F. Wangerein, well known in newspaper circles, and an expert telegrapher, lately employed in this office, died suddenly at his home in Woodhaven, on April 28. The burial took place at Cleveland, Ohio.

The baseball season is in full swing and Mr. R. J. Murphy is in charge of the telegraph arrangements as in former years.

This company has moved into new quarters at 749 Broad Street, Newark, N. J. It also maintains an office in the telephone building on Washington street. Both offices are open day and night. Mr. C. H. Mulford is the Western Union manager and Mr. F. O. Ludlow is the local manager of the New York Telephone Company.

LETTERS FROM OUR AGENTS.

PHILADELPHIA POSTAL NOTES.

Mr. J. P. O'Donohue, division electrical engineer, New York, paid us a visit recently.

Chief operator E. W. Miller went to Baltimore recently on company business.

The Mutual Investment Company of Philadelphia has been organized, with the following officers: finance committee, C. E. Bagley, A. E. Zintl, J. A. McNichol and J. R. Denniston; treasurer, J. A. McNichol; secretary, J. H. Wilson. The membership is limited to 100.

The Bridgeville, Del., office is being overhauled and new fixtures installed.

The Telegraphers' Mutual Benefit Association, 195 Broadway, New York, has for nearly half a century proclaimed the absolute necessity of life insurance and provided a safe and eceonomical form of protection for the home and family within the means of every telegraph and telephone employe. A certificate of membership affording protection of $500 or $1,000, or both, is easily obtainable by every one in good health engaged in telegraph or telephone service, either commercial or railroad, between the ages of 18 and 45, and should be held by all employes not otherwise provided with adequate life protection.

Get Your Own Copy.

Have you been reading TELEGRAPH AND TELEPHONE AGE on and off? That's like being "alive" sometimes and keeping your eyes shut other times.

If you'll write me to send you TELEGRAPH AND TELEPHONE AGE for the next twelve months I'll send it to your home and you will find yourself reading every issue—**and you'll have your own file for reference, too!**

Send me $2.00 (check, money order or stamps) —better **do it now.**

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

Electricity and Magnetism.

The principal reason why so many persons who pursue the study of electricity acquire only a superficial knowledge of the subject is that they devote too little attention to its basic principles, that is to say, the relationship of electricity and magnetism, one with the other, and depend entirely too much upon formulae, instead of getting results through a process of reasoning. They seem to be satisfied with getting the correct answer to the examples given by means of numerous rules, the logic of which is seldom given a thought.

The result is that with books of reference always before them many pass the test satisfactorily, to the gratification of the modern-day teacher, and the subsequent chagrin of the student himself after he learns, as in time he surely will, that formulas are quickly forgotten unless frequently used.

It is usually at a comparatively early stage of progress that the student begins to realize that the only formulas he can readily recall are those which convey a logical meaning to him, or in other words, those relating to examples he thoroughly understands through a process of reasoning. It will thus be seen that formulas are secondary to logic, but each is an aid to the other in the way of compensating elusive memory.

Now, before we endeavor to get at results, or an effect, by means of any given set of rules relating to electricity we should first analyze electricity and see what properties or peculiar actions it possesses that suggest the said rules and formulas.

For example, in the construction of relay and sounder magnets the rule tells us that with a given strength of current flowing through the coils the "pull" or attractive strength of the magnet will increase in proportion to the number of turns or convolutions of wire surrounding the iron core.

If a student is satisfied with that statement alone, and does not ask "why," his knowledge will be merely superficial and he can only figure out the value of a magnet so long as he can bear the rule in mind. If, however, he simultaneously ascertains the reason for such a rule he is not likely to forget the formula, and this will hold good with almost any rule or formula he may encounter. Let us see how a study of the properties of electricity verifies the rule just given.

We will learn that electricity possesses two distinct properties necessary for telegraph operation, one called "current," and the other "magnetism." It is not necessary to waste much time trying to ascertain their nature for the reason that so far no one has been able to solve that question. But we can learn that while the two are inseparable, magnetism and an electric current are each governed by a different law, while in a few cases one rule holds good for both.

Now in all cases for telegraph purposes, except where chemical action is required, it is "magnetism" which operates the instruments, and not the "current," except inasmuch as the current is the creator of the magnetism at work. Hence all of our relay and sounder magnets are constructed with a view of being able to collect and accommodate the amount of magnetism required to operate the armature properly.

Now in order to understand why $P = I \times T$ really gives us the means of regulating the pull or attractive force of a relay or sounder magnet. where P represents the pull, I the current and T the turns or convolutions in the winding, we must first learn where the magnetism or lines of force are to be found and how to collect them.

This question brings us back to an inquiry as to the properties electricity possesses. As previously stated these properties, so far as they apply to telegraph apparatus, are current and magnetism. The current flows through the conductor in volume measured by the electrical pressure and the resistance of the wire, while the latter is surrounded with magnetism, in the form of little rings or circles throughout its entire length. The number of these rings are the same per, say inch,

Digitized by Google

all along the line regardless of the size of the wire. The stronger the current, the more lines per inch will there be.

Now, so long as the magnetic rings are confined to the conductor itself they can do no work in the way we desire. They will not desert the wire for air, brass or nickel under any circumstances, but if we place a bar of iron near them they immediately spread out and circulate through it and thus create what we call a magnet, capable of attracting other iron bars in close proximity to it. In our service this second bar is the armature of the relay or sounder as the case may be.

Now as each inch, or rather, let us say, each length of a turn or convolution of the wire used in winding the iron core possesses a given number of lines of magnetic force, it follows naturally that the total strength of the magnet must be equal to the strength of one turn multiplied by the total number of turns in the coil, as each turn adds its quota to those already in the iron.

As the volume of current regulates the number of magnetic lines collected per convolution, the formula $P = I \times T$ is merely "short-hand" for refreshing one's memory in regard to the information it requires so many words to tell. Hence it should be apparent that in order to acquire a lasting knowledge of electricity the main thing is to learn the "whys" and consider formulas as a secondary aid. If we know the "whys" we can easily recall the formulas.

Telegraph and Telephone Stock Quotations.

Following are the closing quotations of telegraph and telephone stocks on the New York Stock Exchange May 25:

American Telephone and Telegraph Co.	145¾
Mackay Companies	84
Mackay Companies, preferred	69
Western Union Telegraph Co.	83¾

Personal.

Mr. Andrew Carnegie sailed for Europe May 23 on the steamer "Celtic."

Mr. Charles Friedlander, traffic chief, central division of the Associated Press, Chicago, Ill., was a recent New York visitor on business.

Mr. Charles A. Tinker, formerly general superintendent of the Western Union Telegraph Company, New York, has returned from the Pacific coast where he spent the winter.

Mr. J. F. Gormley, of Canton, Mass., an old-time telegrapher, is suffering from cataracts in both eyes and will be operated on soon for their removal.

Mr. J. E. Wright, the well-known old-time telegrapher and inventor of the printer system known by his name, is now located at Swissvale, Pa., where his printing telegraph machines will be built in the future by the Union Switch and Signal Company.

Messrs. F. Douglas Watson, general manager and secretary, A. S. Duncan, assistant electrician and A. Podmore, assistant engineer to the Constantinople Telephone Company (Société Anonyme Ottomane des Téléphones de Constantinople), have left London for Constantinople to take up their duties.

Mr. and Mrs. David Homer Bates, jr., will be "at home" at The Ansonia, New York, after June 15. Mr. Bates is the son of Mr. David Homer Bates, secretary of the Society of the United States Military Telegraph Corps, and was married on May 15 to Mrs. Eleanor Loring Lord.

Mr. Wm. B. Vansize, a well-known old-time telegrapher, but for the past thirty years a patent expert, has opened offices at 31 Nassau St., New York. Mr. Vansize has had a wide experience in soliciting patents in the United States and foreign countries and many years' experience as a patent expert in litigated cases and in assisting counsel.

Mrs. Marguerite C. Gates, of New York, a former telegrapher and a member of the Old Time Telegraphers and Historical Association, was present, on invitation, at the launching of the United States battleship "Texas" at Newport News, Va., May 16. Mrs. Gates was also present at the unveiling of the telegraph monument at Harriman, N. Y., May 2, and was one of the first contributors to the fund.

Brigadier-general James Allen, chief of the United States Signal Corps, Washington, D. C., and head of the army aviation department, took his first ride in a hydro-aeroplane around New York harbor May 15, to study the performance and applicability of that type of machine to war purposes. He was a passenger, and received a slight ducking in New York bay during the manœuvres. The trip included an aerial circle around the Statue of Liberty, and the machine was kept in perfect control.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. Clarence H. Mackay and his mother, Mrs. John W. Mackay, have donated $150,000 to the University of Nevada, making their total benefactions to this institution $400,000.

Mr. Clarence H. Mackay has presented to the New York Zoological Society a collection of mounted heads of large game captured in the West and on the Kenai peninsula, Alaska.

Mr. E. J. Nally, vice-president and general manager, has returned to New York after an extensive trip through the West and South.

Mr. E. W. Collins, general superintendent, Chicago, is making an extended business trip throughout his division, visiting offices in Colorado, Utah, Wyoming, Arizona, Texas and New Mexico. He will return to his office early in June.

The recent executive office visitors included Mr. Henry Scrivens, superintendent, Pittsburgh, Pa.; C. E. Bagley, superintendent, Philadelphia, Pa.

The Mackay Telegraph and Cable Company has filed a petition in the United States District Court at Little Rock, Ark., asking that the city of Hot Springs, Ark., be enjoined from interfering with the construction of its lines along the streets of that city.

Mr Edwin Stanton Williams, who, as announced in our issue dated May 16, was appointed district superintendent of the Postal Telegraph-Cable Company, with headquarters at Chicago, Ill., was born at Oak Hill, Ohio, April 14, 1866, and began his telegraphic career in December, 1882, as a messenger in the Baltimore and Ohio Railroad and commercial office at Oak Hill. In April, 1883, he became an operator for that road at Webster, and later went to Sciotoville, Ohio, afterward being employed on various other railroads in the West. Between 1884 and 1890 he was in the commercial service as operator for the Western Union at St. Paul, Minneapolis and Duluth, Minn., and in April of the latter year joined the forces of the Postal Telegraph-Cable Company in Chicago, serving successively as

E. S. WILLIAMS,
Superintendent Postal Telegraph-Cable Company, Chicago.

operator, assistant chief, chief operator and manager of the Board of Trade office and finally in January, 1907, becoming manager of the main office, which position he held at the time of his appointment as superintendent.

Postal vs. Western Union.

On May 20 the New York Public Service Commission, Second District, at Albany, heard the complaint of the Postal Telegraph-Cable Company against the Western Union Telegraph Company alleging discrimination and unreasonable charges by the Western Union on messages transmitted part way by the Postal Company and then turned over to the Western Union for transmission to destination. The Postal Company was represented by Messrs. W. W. Cook, general counsel; R. H. Overbaugh and John A. Delehanty, associates; C. C. Adams, second vice-president and Isaac Smith, superintendent of tariffs. The Western Union Company was represented by Messrs. Newcomb Carlton, vice-president; Rush Taggart, general counsel; J. C. Willever, United States manager cable system; Wm. Holmes, superintendent of tariff bureau; W. N. Fashbaugh, traffic engineer; R. G. Wilson, manager of the receiving and delivery department, and F. D. Giles of the commercial superintendent's office. Briefs are to be filed by counsel some time in June. The commission's decision will be awaited with much interest.

Mr. F. A. Mohr, manager of the Western Union Telegraph Company at Milwaukee, Wis., writes: "I am glad you renewed my subscription to TELEGRAPH AND TELEPHONE AGE, as it would be like losing an old and tried companion to have it stopped."

Digitized by Google

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr. Theo. N. Vail, president of the American Telephone and Telegraph Company and of the Western Union Telegraph Company, has been elected a director of the United States Rubber Company.

Mr. Newcomb Carlton, vice-president, has returned from a business trip which took him as far as the Pacific Coast.

Mr. C. F. Ames, district commercial superintendent, Boston, Mass., reports the following appointments in his district: F. W. Barth, formerly plant chief at New Haven, Conn., manager at Boston, Mass.; J. H. Harrigan, manager at Gloucester, Mass., vice J. C. Bonner who becomes cashier at Worcester, Mass.

Mr. J. R. Terhune, district superintendent, Nashville, Tenn., reports the following appointments at that point: Mr. C. W. Chenault, formerly manager at Ashland, Ky., district manager; Mr. H. H. Kirkpatrick, district cable manager, and Mr. E. S. Ridgeway, district traffic supervisor.

Mr. A. C. Terry, district commercial superintendent, Pittsburg, Pa., was a recent executive office visitor.

A conference of superintendents was held in Chicago, May 13.

Mr. G. F. Hoyte, who has charge of the *New York Times* telegraph bureau for this company, has returned from a two weeks' trip to Chicago.

Mr. C. H. Simpson, formerly manager at Brooklyn, N. Y., has been transferred to Worcester, Mass., as manager, vice Mr. W. E. Dickinson, transferred to superintendent Mulford's office, New York.

Mr. S. F. Shutt, assistant manager at Baltimore, Md., has, on account of ill health, been obliged to resign that position and apply for leave of absence, with the intention of taking a needed rest in the country, where he hopes to recover his health. He is succeeded by Mr. J. Tyson Sheldrake, formerly in the office of district plant superintendent R. J. Meigs of Philadelphia.

Printers have been installed between Denver, Col., and El Paso, Tex., with repeaters at Las Vegas, N. M.

A conference of Western Union superintendents and managers was held in the offices of district superintendent J. R. Terhune, Nashville, Tenn., May 20 and 21. The proceedings were conducted by Mr. Terhune and in the evening of May 20 a banquet was held at the Hotel Hermitage, Mr. Terhune acting as toastmaster. Those present, besides Mr. Terhune were: L. E. Rudd, manager, O. Stanley, commercial agent, and J. E. Lively, chief operator, Memphis, Tenn.; Charles Smith, manager, C. H. Carroll, district manager, and D. G. Breed, chief operator, Louisville, Ky., H. J. Carpenter, commercial agent, W. H. McClarrin, district plant manager, H. H. Kirkpatrick, district cable manager, E. S. Ridgeway, district traffic superintendent, C. W. Chenault, district manager, Wm. Bloomstein, assistant manager, T. B. Adams, chief operator, J. F. Fleming, night chief operator, A. F. Raymer, secretary and L. E. Pearce, chief clerk to superintendent Terhune, J. F. Grainger, chief clerk, Miss Ogilvie, cashier, Misses Howell, Williams and Mulligan, operators, and others of the Nashville office. J. B. Cheatham, special agent, Atlanta, Ga.; S. G. Quisenberry, manager, Paducah, Ky.; H. W. Whitsitt, district manager, and L. K. McNees, manager, Jackson, Miss.; J. S. Berger, manager, Lexington, Ky.; T. H. Gore, manager, Knoxville, Tenn.; R. H. Tudor, manager, Chattanooga, Tenn.; A. T. Cocke, manager, Meridian, Miss., and T. S. Bogan, manager, Bristol, Tenn. E. M. Fisher, special agent, and K. C. Hardcastle, traffic superintendent, of Nashville, represented the Cumberland Telephone & Telegraph Company.

Mr. T. A. Darling, whose appointment as manager of the Western Union Telegraph office at Fort Worth, Tex., was announced in our issue for May 16, was born in Whistler, Ala., April 8, 1872, and entered the telegraph service at Mobile, Ala., in February, 1891, for the Western Union Company. In 1894 he joined the ranks of the Postal Telegraph-Cable Company at New Orleans, La., and in 1901 went with the Postal Telegraph-Cable Company of Texas at Beaumont, Tex. On May 1, 1912, he returned to the Western Union service at Fort Worth, Tex.

Mr. Charles H. Simpson, recently appointed manager at Worcester, Mass., was born at Lima, N. Y., March 1, 1877, and entered the telegraph service in July, 1895, as operator for the New York Central Railroad at Victor, N. Y. In 1898 he took a position in the train dispatcher's office at Rochester, N. Y., and worked for that road at different points in various capacities until 1906 when he became manager of the Western Union office at Batavia, N. Y. On May 1, 1909, he was appointed manager at Niagara Falls, N. Y., and on September 1, 1911, was transferred to Brooklyn, N. Y., as manager, which position he held at the time of his appontment to Worcester.

Mr. J. B. Dillon, of Dallas, Tex., writes: "I wish to thank you for renewing my subscription to our mutual benefactor. The AGE, and I have gone hand in hand since I was a messenger boy and it shall forever be to me the same good cheering missive. A person in the telegraph business without TELEGRAPH AND TELEPHONE AGE is only half schooled, and will never be a graduate without it, for a little learning is a dangerous thing. The AGE fills the wants of all and pleases the most fastidious, and it makes one familiar with what a telegrapher should know, regardless of his title."

Mr. William Arnott, of Cleveland, Ohio, writes: "TELEGRAPH AND TELEPHONE AGE contains more information of general wireless news that I can get anywhere else. Enclosed find $2.00 for renewal of my subscription."

Digitized by Google

The Cable.

Mr. G. G. Ward, vice-president and general manager of the Commercial Cable Company, New York, accompanied by his wife, sailed for England on the steamer "Celtic," May 23.

Seventeen Minutes from New York to Argentina.—Mr. B. H. Reynolds, superintendent of the Central and South American Telegraph Company, New York, made an address before the Pan-American Trade Conference at the Waldorf-Astoria hotel, New York, May 16. He stated that Argentina is only seventeen minutes from New York.

Italian-Tunisian Cables.—An agreement has been reached between the Italian Government and the Eastern Telegraph Company in regard to the vested interest held by the company, covered by its contract with the Turkish Government, for operating the cable between Tripoli and Malta. The Italian Government, in consequence, is commencing to lay a cable between Sicily and the port of Tripoli, to be followed by a cable between Sicily and Benghazi. It is stated that the Italian Government intends to connect Benghazi and Tripoli by a cable within a few months. The Italian Government has authorized the construction of a submarine cable between Sicily and Tripoli.

The Telephone.

Mr. N. C. Kingsbury, vice-president of the American Telephone and Telegraph Company, New York, made an address before the Philadelphia Telephone Society recently on the subject of corporation publicity. Remarks were also made by Messrs. F. H. Bethell, president, and P. L. Spalding, second vice-president, of the Bell Telephone Company of Pennsylvania; U. N. Bethell, president New York Telephone Company, New York, and E. D. Nims, vice-president of the Southwestern group of Bell companies.

Mr. Leland Hume, general manager of the Cumberland Telephone and Telegraph Company, Nashville, Tenn., addressed a "booster" meeting at Jackson, Miss., May 13.

Automatic Telephones in Lincoln.—The Lincoln Telephone and Telegraph Company, Lincoln, Neb., has decided to substitute an automatic system of telephony for the present manually-operated system.

Women Cashiers at Telephone Headquarters.—Twenty men in the offices of the auditor of the New York Telephone Company, New York, have been replaced by women. The men have been transferred to outside work as solicitors.

Telephones in Durban, South Africa.—Durban has the only municipal telephone system in the Union of South Africa. All others are owned and operated by the Union Government. Durban is also the only city of the Union which uses American telephones. All other cities use the Ericsson, a Swedish telephone.

Notes on Telephone Exchange Equipment.—Mr. Alex. J. Gayes, of London, on May 10 read a paper before the Junior Institution of Engineers in London entitled "Notes on Telephone Exchange Equipment." The paper was very fully illustrated with diagrams of circuits, etc. It deals largely with the London system, and it points out that the first telephone exchange in London was opened thirty-three years ago, with eight subscribers.

Telephone Rights in Louisville.—The Supreme Court of the United States on May 13 approved the action of the Federal Circuit Court for Western Kentucky, in permanently enjoining the city of Louisville from removing the telephone equipment of the Cumberland Telephone and Telegraph Company from its streets. The Supreme Court held that the company possesses its rights to use the streets under the State charter and not under the city ordinance.

Telephone Rates Between England and France.—A fifty per cent. reduction in telephone charges between England and France has not yet, according to a recent statement of Mr. Herbert Samuels, British Postmaster-General, been effected, because the new cables have not yet been connected by land lines to Paris. Steps were being taken, he said, to extend telephonic communication with the continent, and it would not be long before London was in communication with Berlin.

Dinner to Mr. J. P. Crowley.—Mr. J. P. Crowley, secretary of the Southwestern Telegraph and Telephone Company, was the guest of honor at a dinner tendered to him in Dallas, Tex., May 8, prior to his departure for St. Louis, Mo., which city will henceforth be his headquarters. Vice-president and general manager Joseph E. Farnsworth acted as toastmaster. Addresses were made by Messrs. C. A. Gates, J. E. Farnsworth, F. E. Shoup, P. K. Baker, T. J. Moseley and W. D. Keniston.

Telephone Papers Before the A. I. E. E.—At the Pacific Coast meeting of the American Institute of Electrical Engineers, held in Portland, Ore., April 16-20, three papers of interest to telegraph and telephone engineers were read. Mr. Alfred H. Dyson presented a paper entitled "The Application of Automatic Selecting Devices to Telephone Multiple Switchboards;" Mr. A. H. Griswold one on "Design of Telephone Pole Lines for Conditions West of the Rocky Mountains," and the third, entitled "Practical Joint Pole Construction," by Mr. J. E. Macdonald.

Telephone Conference.—A conference of officials of the commercial department of the Southwestern Telegraph and Telephone Co. was held at Dallas, Tex., May 8. Among those who attended were: General commercial superintendent P. K. Baker; M. J. Stimson, division superintendent, Little Rock, Ark.; W. W. Vaughan, division commercial superintendent, San Antonio, Tex.; E. G. Pike, division commercial superintendent, Houston, Tex.; W. C. Maas, division commercial

Digitized by Google

superintendent, Dallas, Tex.; M. P. Campbell, assistant division commercial superintendent, Fort Worth, Tex.; F. B. Knight, special agent in charge of publicity, D. C. Rosser, commercial engineer, and C. H. Abbott, special agent commercial department, Dallas, Tex.

Mountain States Telephone & Telegraph Company.—In its report for its first seven months' operation, the Mountain States Telephone & Telegraph Co., Denver, Col., shows 178,745 stations, March 1, 1912, a gain of 15,810 in seven months; 396,915 miles of exchange wire and 68,987 miles of toll wire, a gain of 58,314 miles of the former and 10,158 miles of the latter Earnings for the seven months ended Feb. 29, 1912, were $3,679,562, as against $3,348,209 for the preceding seven months under old organization, or a gain of $331,353. Expenses were $2,393,347, a gain of $44,820, leaving net earnings for seven months $1,286,215, a gain of $286,553. The balance sheet shows a total investment of $25,942,176, with surplus and reserves aggrevatng $4,459,400. Mr. E. B. Field, president of the company, states that the seven months have shown a gain of 9.7 per cent. in stations, of 9.9 per cent. in gross revenue, of 28.6 per cent. in net revenue, 7.7 per cent. in total investment, 47 per cent. in surplus and reserves.

Radio-Telegraphy.

Wireless in Venezuela.—Wireless stations are to be established at La Guaira, Puerto Cabello, Maracaibo and Cumana, Venezuela.

Marconi Honored by Spanish King.—King Alfonso of Spain received Signor G. Marconi on May 20 and conferred upon him the Grand Cross of the Order of Alfonso XII.

Rapid Wireless Preparations.—It is stated that the signal corps at Ft. Myer, Va., can unpack its wireless machine, erect the antenna, forty feet high, and begin work in sixty-eight seconds.

Wireless Operators in the Navy.—Expiring enlistments in the navy are causing a scarcity of wireless operators, and special efforts are being made to secure new recruits for this branch of the service.

Marconi School of Instruction.—The Marconi Wireless Telegraph Company of America is establishing a school of instruction for operators at 29 Cliff Street, New York. The theory as well as the practice of wireless telegraphy will be taught.

To Teach Wireless Telegraphy in Chicago.—It is stated that wireless telegraphy is to be taught in the Chicago high schools. The Government should nip these silly schemes in the bud if it wants to prevent interference with legitimate wireless business.

Fined for Violating the Wireless Law.—Captain L. D. Johnstone, of the steamer "Sabine" of the Mallory Line, which steamer is in the coast trade was on May 22 fined $100 by Judge Mayer in the District Court, New York, for going to sea without a wireless operator. The offense occurred December 28, 1911.

Wireless Station at University of Michigan.—The University of Michigan, at Ann Arbor, maintains a completely equipped wireless telegraph station. The station has a wide operating range and has communicated with Cleveland and other cities nearer by.

Three Wireless Operators on the "Imperator."—Three wireless operators will be carried on the new steamer "Imperator" of the Hamburg-American line which was launched at Hamburg, Germany, May 23. This steamer is the largest ever constructed.

Wireless Telegraphy at Sea.—It is stated that since the beginning of 1909 the passengers on twenty-two shipwrecked vessels have owed their lives to the fact that the ships were equipped with a wireless telegraph system, and were consequently able to send out messages for assistance.

Wireless Telegraphy in Central America.—The National Electric Signal Company, of Pittsburgh, Pa., is taking up the matter of establishing a number of wireless stations along the Atlantic coast of Mexico and Central America with the purpose of obtaining constant communication between these countries and the United States.

Injunction Against Wireless Company.—The Marconi Wireless Telegraph Company has asked the United States District Court, New York, for an injunction against the National Electric Signalling Company of South Brooklyn on the ground of infringement of certain patented devices, rights, etc., owned by it.

Wireless on the Isthmus.—The United States Government is planning to spend $1,000,000 for wireless equipment at the Isthmus of Panama, and it is stated that arrangements have been made with the republic of Panama to prevent any private or commercial wireless companies from establishing stations in that country.

The Marconi Wireless Telegraph Company of America recently started a campaign of advancement by bidding on and taking contracts to supply the U. S. Government with radio communication apparatus, and placing before the public a line of experimental radio apparatus, at the same time employing engineers capable of carrying out this and other work.

Marconi Sues for Libel.—Signor G. Marconi and Mr. G. C. Isaacs, managing director of Marconi's Wireless Telegraph Company Limited, London, have sued the Berlin newspaper *Welt Am Montag* for libel contained in an article accusing them of exploiting the "Titanic" catastrophe for the company's benefit by holding out news for sale, etc.

Special Power Plant for Ship Wireless.—The new steamer "Megantic," of the White Star Line will be provided with a special generating outfit for the wireless equipment. The electric generator is driven by a gas engine, and will furnish current to light the ship and operate the wireless when accident has rendered the regular power equipment useless. The special equipment has been installed on the upper deck.

Digitized by Google

No More Love-Making by Wireless.—It is stated that a Government censorship of wireless messages has been established at Newport, R. I., in order to stop the sending of love messages from women ashore to sailors on ships. One Boston girl asked her "Darling Jack," who was with the fleet, to come back to her as soon as possible because she had not been kissed in so long a time that her lips were dry. The unsentimental Government authorities state that important business has been interfered with by trivial messages.

Federal Telegraph Company.—The Federal Telegraph Company of San Francisco, Cal., which uses the Poulsen wireless system, has acquired the exclusive rights for the United States, Alaska, Cuba, Panama, Porto Rico, Hawaiian Islands and Philippine Islands, and the transmarine rights of Vlademar Poulsen, of Copenhagen. It is stated that a speed of 400 words per minute is possible by this system. The Federal Company now has fourteen stations on the Pacific Coast and it is stated the company will establish stations throughout the United States for overland commercial service. Its factory and laboratories are at Palo Alto, Cal.

The Sale of United Wireless.—The United States Circuit Court of Appeals at Boston, Mass., on May 3, declined to permit the sale of the United Wireless Telegraph Company now in bankruptcy. The court based its decision on the fact that the property of the United Wireless Telegraph Company is now in litigation in the Court of Appeals in connection with a suit of alleged infringement of patent, brought by the National Electric Signaling Company. It is stated that this decision will not necessarily prevent the sale; that the prohibition applies only to apparatus involved in patent litigation, and is effective only until that suit is decided or until the further order of the court.

English Wireless Affairs.—Postmaster-General Samuels, of Great Britain, stated in the House of Commons, May 20, that the question of compulsory wireless installation on ships and the conditions that should be imposed for continuous service were matters that were engaging the close attention of the president of the Board of Trade and himself. Probably they would be considered at the International Conference on Wireless Telegraphy in London, June 4. Provisional arrangements, he added, have been made with the Marconi Company for the erection through the British Empire of wireless stations able to communicate with each other at a distance of 2,000 miles or more. Six stations would be erected at first. The cost in round figures for each station, excluding the sites of the buildings, would be £60,000 ($300,000).

Regulation of Wireless.

At a meeting of the Ohio State University Association of New York May 4, Mr. R. H. Marriott read from some of his notes and papers on wireless communication, gathered during eleven years' experience as an engineer in this field. He made some suggestions as to proper wireless regulations, among which are that each vessel be provided with at least three operators; that wireless operators be classified as (1) electrician operators; (2) expert wireless telegraph operators, and (3) wireless telegraph operators, and the use of certain wave lengths for distress calls.

The Late J. G. Phillips, Wireless Operator on the "Titanic."

John George Phillips, the wireless operator who lost his life in the disaster which overtook the "Titanic" on April 15, was born April 11, 1887, in Farncombe, Godalming, England. He was educated in the Godalming Grammar School and in 1902 became a student of telegraphy in the local postoffice under Mr. W. R. Williams, postmaster at Godalming. Phillips was a serious and efficient worker and gained the esteem of his superior officers. In 1906 young Phillips passed the examination admitting him to the Marconi Company's school at Liverpool and after two years' training took the examination which would qualify him for a position as operator on

THE LATE JOHN GEORGE PHILLIPS,
Senior Wireless Operator on the Steamer "Titanic."

one of the large steamships. In this test he stood at the head of the list of successful candidates and was shortly afterward appointed operator on the "Teutonic." Subsequently he served on the steamers "Mauretania," "Lusitania," and "Oceanic." On the "Titanic" he held the position of chief operator on her first and only voyage, and lost his life in the performance of his duty during the catastrophe which overtook that vessel.

The Godalming town council has taken steps to establish a memorial to Phillips and public subscriptions are now being received for the purpose.

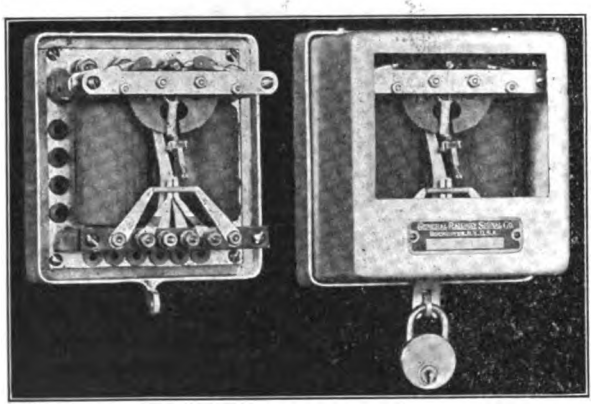
Selective Signaling System on Rochester Division, New York Central and Hudson River Railroad.

There was placed in service on the Rochester Division of the New York Central and Hudson River Railroad, April 20, a system of selective calling for telephone train dispatching differing radically from the general run of selective calling systems. The dispatcher's office equipment is shown in Fig. 1. This circuit extends from

FIG. 1.—TRAIN DISPATCHER'S OFFICE EQUIPMENT AT ROCHESTER, N. Y.

Rochester, N. Y., to Suspension Bridge, N. Y., a distance of 76.4 miles, which, together with its loops, makes a circuit of approximately 90 miles. The telephone equipment consists of Western Electric telephones with Van Akin arms. Among the many advantages of this arm, it requires the operator to talk directly into the transmitter; it also does away with the cord troubles incident to other makes of arms. There are thirty-three General Railway Signal Company selectors on this circuit. The dispatchers are located at Rochester, N. Y.

The system is known as the G. R. S. System and consists of three units, as follows: 1st. the

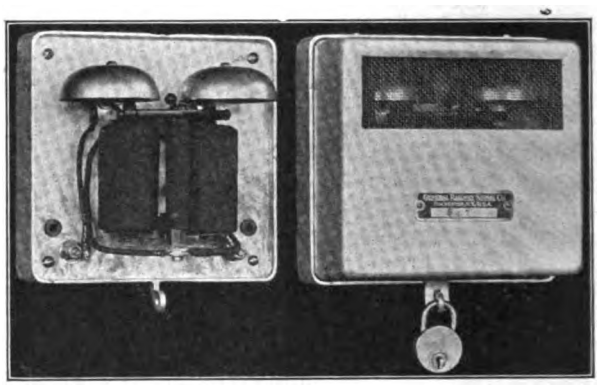


FIGS. 2 AND 3.—SELECTOR WITHOUT AND WITH COVER.

selector and bell located in the way stations; 2nd. the individual key cabinet in the dispatcher's office; 3rd. the motor generator, switchboard and battery located in a supply room approximately 300 feet from the dispatcher's office.

The selector, shown in Figs. 2 and 3, is a two-sector polarized device; the magnetic circuit is so designed that the flux always flows in a direction to build up the magnetism of the permanent magnet, thus overcoming the principal objection to permanent magnets, which is, that in time they may become demagnetized. Such trouble cannot occur in this device. Two sectors are used instead of one in order to attain greater speed, reliability and economy than is possible with one sector; these three results are most certainly attained. The selector is adjustable to any combination in the range of 324 without removing it from the wall; that is, it is not necessary to return it to the factory or change the key in the dispatcher's office should a change in the combination or call be desired. The coils of the selectors are form-wound, that is, wound on a mandrel and placed on the cores in assembling, not spool wound on the cores.

The selector is mounted in a dust-proof macadamite case with a glass front so that the working of the selector may be observed without



FIGS. 4 AND 5.—BELL WITHOUT AND WITH COVER.

removing the cover. The cover is held in place by a padlock so that the maintainer may, if necessary, get at the apparatus for inspections, tests or change of combination. The external resistance unit for balancing the line is contained in a brass cup in the back of the selector and has a great range of resistances; this is considered a part of the selector.

The magnetic circuit of the selector is unique in that it has but one air gap where ordinarily there are two. The armature swings from the center and is supported on a knife-edge bearing which is an extension of the permanent magnet. The contacts are of platinum-iridium and are of the rubbing, self-cleaning type.

Each selector is sent out equipped to operate two local circuits and may be made to operate six local circuits by simply substituting a six-circuit block for the two-circuit block regularly furnished. The magnetic circuit and armature of the bell is similar in construction to the selector, except that the bell is not polarized. The bell is extremely loud in operation and there is no possibility of mistaking it for the ordinary telephone bell. The bell, which is shown in Figs. 4 and 5, is

Digitized by Google

mounted in a case similar to the selector, except that a brass screen is substituted for the glass in the front to allow the egress of the sound waves.

All binding posts of selectors and bells are inside of the cases and protected by the padlocks, thus preventing unauthorized persons from tampering with or changing connections. The individual key is similar to a messenger call with additional discs for opening and closing the circuits of the motor control and line control relays.

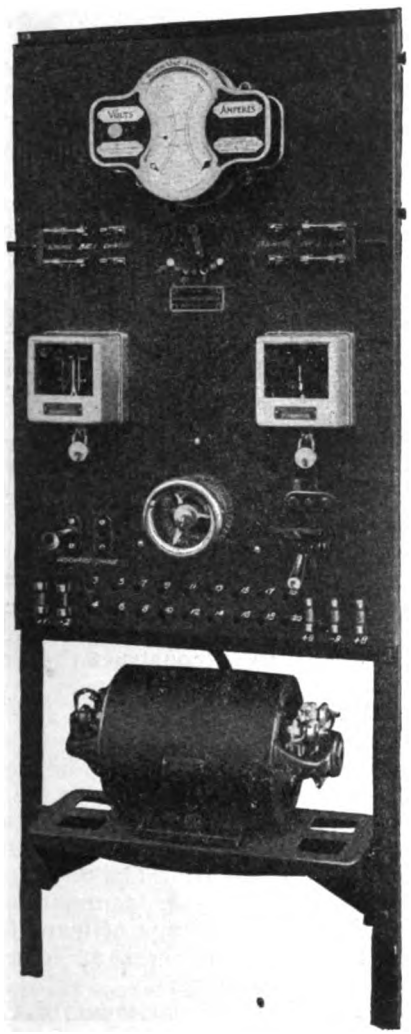


FIG. 6.—SWITCHBOARD, FRONT VIEW.

The switchboard and motor-generator set is shown in Fig. 6, front view, and Fig. 7, rear view. This equipment is made up in accordance with Underwriters' Rules and Regulations and includes the following apparatus: line control relay, motor control relay, volt-ammeter, switches for charging and discharging two sets of battery, ammeter jacks for charge and discharge current, underload circuit breaker, voltmeter-switches, retardation coils, condensers, field rheostat for generator and motor-generator.

The operation of the key is as follows: The first movement or setting of the key closes a circuit to the motor control relay, thus starting the motor generator set. As the key returns toward the normal position, toothed discs make contacts with the positive and negative contact springs operating the line control relay which sends the impulses to line operating the selectors and ringing the bell at the selected station. At the completion of the travel of the key the motor relay contact is opened and the motor generator stops. It will thus be seen that the motor generator is started and stopped with each call and runs only during the sending of a call. The main battery of six cells of eighty ampere-hour storage battery is all that is used in this system. The cost for current for charging this battery on a circuit having an average of 300 calls per day with current at 10c. per kilowatt hour, is less

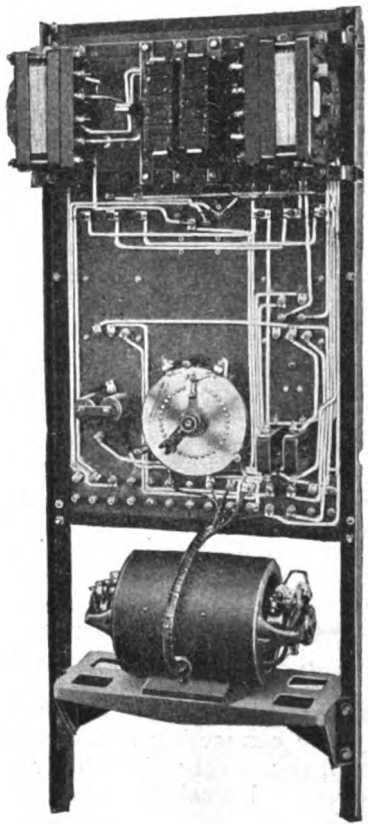

FIG. 7.—SWITCHBOARD, REAR VIEW.

than $3.00 per year. If continuous 110-volt direct current or 220-volt direct current is available the battery can be floated on charge and will require no attention, except an occasional filling of cells with distilled water to replace evaporated solution. If alternating current is available, then the battery is charged through the medium of an alternating current-direct current motor generator set of very small capacity. The battery is charged but once a month. If neither alternating current nor direct current is available, the battery may be floated on charge from gravity battery, the same as is done in signal work in many cases. It will thus be seen

Digitized by Google

that the scheme of a small number of storage cells for a main battery may be used under all circumstances. With this motor generator storage battery scheme a great range of line voltage is available at all times. The line voltage may be raised or lowered at will, simply by turning the field rheostat arm of the generator. The generator is compound-wound so that a constant line voltage at any required point is maintained.

The key is silent in its operation and the line relay is mounted on the switchboard instead of in the dispatcher's office as is the usual practice. The operation of the line relay is silent and therefore could be mounted in the dispatcher's office if desired. In this system the switchboard, motor-generator and battery are located at any convenient point in the battery room or store room, cellar or attic, and the individual key cabinet is the only piece of apparatus placed in the dispatcher's office.

The General Railway Signal Company has recently brought out two other schemes to be used in connection with telephone train dispatching circuits. One is the sending of time over the telephone circuit and the other the connecting of adjoining train dispatching circuits together through the medium of a remote control relay located at the terminal point. In the time service the vibrating bells at the stations are automatically changed over to single-stroke bells while the time is being sent and the time is tapped off on one gong. This change is made by an individual key at the dispatcher's office in the key cabinet and a contact on each selector at the way station.

The connecting of one dispatcher's circuit to another so that dispatchers in adjoining districts may be in direct telephonic connection is now in service on the Illinois Central Railroad on the Water Valley, Miss., to Jackson, Tenn., circuit, and the Jackson, Tenn., to Mounds, Ill., circuit. This permits the dispatchers to get a "line up" without going through the terminal operator and gives them the advantage of direct personal conversation. The connecting and disconnecting is done at will by either dispatcher by simply operating a key in his cabinet.

Institute of Radio Engineers.

On the evening of May 13, the Wireless Institute and the Society of Wireless Telegraph Engineers held a joint meeting at Columbia University, New York, and combined under the new constitution and under the name of Institute of Radio Engineers. The following officers were elected: R. H. Marriott, president; Fritz Lowenstein, vice-president; Emil Simon, secretary; E. D. Forbes, treasurer. Board of Directors: G. W. Pickard, William Sphar, John L. Hogan, Jr.

Committees on standardization, papers and publicity were appointed.

Mr. Marriott exhibited charts showing symbols relating to radio communication and urged that the Institute take up the matter immediately as the art apparently is in need of standard symbols and nomenclature.

A meeting of the Institute was held May 20. Mr. F. Lowenstein, Mr. Clark, of the U. S. Navy Department and Mr. Weagant of the Marconi Company of America spoke quite strongly in favor of making the national logarithmic decrement of oscillations a numeric not greater than 0.2 per period.

Mr. Marriott exhibited a chart in which he showed that of 104 representative ocean-going vessels less than ten could use a wave length as short as 300 meters without materially decreasing the radiation. He suggested that distress calls be sent on twice the average natural period, which seems to be the wave length for which the open circuit and radiation resistance are least. From Mr. Marriott's data this would make the distress call wave length about 740 meters. This wave length would of course be affected less by absorption than the 300-meter wave length which has been proposed.

Mr. Marriott spoke strongly in favor of making emergency apparatus equal to or greater in strength than the apparatus used under ordinary circumstances.

Mr. Sphar and Mr. Fay of the American Bell Telephone and Telegraph Company said the London convention should define the Continental code and abbreviations which are to be used.

Dr. Goldsmith, of the College of the City of New York, spoke very emphatically along the lines of compelling all companies, where engaged in communication with vessels, regardless of the system employed, to so construct their apparatus that they would receive and answer any distress signals that might be sent out.

The general opinion of the Institute seemed to be that all considerations for radio regulations should be based on the rendering of the best possible wireless service particularly in times of distress, and that on this basis alone could the art be made of greatest benefit to humanity.

It was also agreed that commercial vessels should be given a wide range of wave length for handling commercial business at least no less than from 400 to 800 meters.

Mr. Kolster of the Department of Commerce and Labor and an advisory delegate to the International Convention took an active part in the discussion.

Resolutions were passed regarding the death of Mr. John Phillips the chief operator of the steamer "Titanic."

The Institute expects to publish its papers and the best papers of the Wireless Institute and Institute of Wireless Telegraph Engineers.

T. M. B. A. Assessment.—Assessment No. 538 has been levied by the Telegraphers' Mutual Benefit Association to meet the claims arising from the deaths of E. S. Briner, at Dallas, Tex.; E. E. Shawn, at Denver, Col.; Maurice Brick, at Washington, D. C., and D. D. Kennedy, at Baltimore, Md.

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

June 1, 1912.

Welcome to the Railway Telegraph Superintendents.

In coming to New York for their thirty-first annual convention, the Railway Telegraph Superintendents and their families will receive a cordial welcome. New York is a highly concentrated city, but it has a very large capacity, and the temporary addition to its vast population of a few hundred persons will not disturb the balance. There is an abundance of room for all, and there need be no fear of eating the town out.

The programme, as set forth on another page of this issue, is well planned. The superintendents came here primarily to work, but ample recreation has been provided for them during breathing spells. There is much to see in a city like New York, and it is not an easy task to arrange a programme combining business with pleasure that will give general satisfaction, but the entertainment committee has succeeded very well indeed in its efforts to achieve this result, and we hope that all will enjoy their stay in the metropolis.

The papers to be read are of the highest quality and extremely practical. Sometimes papers presented before technical bodies are models of diction and have a pleasant ring to them, but are of little practical value; the latter charge cannot be truthfully made, however, against the papers that the superintendents are to hear and discuss. They are prepared by level-headed and practical men on practical matters and they will add much to the fund of knowledge on the subjects with which they deal. Railway telegraph superintendents are not theorists; they are extremely practical, and nothing but a diet of facts will satisfy them.

At the last moment the committee of arrangements cut out the clambake from the programme, for the alleged reason that they could not secure a sufficient number of automobiles to convey the party to the scene of action, but we suspect that the real cause was the inability to find enough clams to go around. However, be that as it may, an excellent substitute has been provided. Those who have a penchant for clams can find them in almost any restaurant in New York, but this cannot be said of Martin banquets.

Thirtieth Year of Telegraph and Telephone Age.

The present issue of TELEGRAPH AND TELEPHONE AGE marks the beginning of the thirtieth year of the journal's existence and another period of usefulness in its chosen field of activity.

Starting from a small beginning it has gained experience and strength until now it has reached a stage in its career where it stands at the head of its kind.

It is not only the success of the paper as a business enterprise that counts, however. Be it far from us to place that achievement above everything else; the moral side we consider the more important. The first care of the paper has always been one calculated to do the most good to the greatest number of its readers, and it has tried to inspire and encourage its readers to higher and nobler thoughts and deeds, and we believe that our efforts have not been amiss.

Looking back over thirty years one is profoundly impressed with what electricity has accomplished for mankind through the agency of man. Thirty years ago the telegraph occupied the electrical field largely by itself. Since that time, however, the telephone, the electric light, the electric railway, wireless telegraphy and other applications of electricity have come into existence and grown to be great industries. They all occupy distinct fields of activity, but, together with the telegraph, all depend for their existence upon one and the same mysterious force—electricity.

What the next thirty years will bring forth no man knows, but it is certain that progress and development along electrical lines will not halt, but will be as great, at least, as that of the past thirty years.

It is the ambition of the proprietors of TELEGRAPH AND TELEPHONE AGE to maintain its leading position in its chosen field, as in the past. We feel greatly encouraged in our work by the favorable conditions existing in those departments of electrical activity with which the paper is chiefly concerned. The telegraph has outgrown the limitations of former years and is taking its place among the most vital and active forces in the business realm of the world. Under organized and intelligent guidance it is becoming more and more an open book to the popular mind, and its value and utility as a means of conveying intelligence between distant points is becoming rapidly appreciated. As to the robust telephone little need be said, as everyone knows about it. The telegraph and the telephone are real necessi-

Digitized by Google

ties in present-day business and social life, and the outlook for their future is most encouraging.

We believe that our efforts in the past toward the upbuilding of these two great industries have been appreciated, judging by the generous support and encouragement extended to us. It is needless to say that such encouragement has always touched a responsive chord, and has spurred us on to greater endeavors, and we hope that the bond of relationship between the paper and its readers will become more firmly cemented as the years roll by.

The Standing of Wireless on Steamers.

It would seem that every seafaring man concerned directly or indirectly with the "Titanic" disaster was affected by an evil influence which blunted his senses and judgment, resulting in unpreparedness for emergencies.

The investigation into the disaster, which is now being conducted in London, reveals woeful neglect of duty and lack of judgment on the part of many of the principals immediately and indirectly concerned.

It appears that the steamer "Californian" was only a few miles from the "Titanic" when the latter sent out distress signals, and yet through some hypnotizing influence the officers of the former became dreamy and generally inactive

While they were speculating as to the cause of the unusual appearances, the "Titanic" sank, with hundreds of lives that might have been saved had the officers of the "Californian" been possessed of their wits and on the alert.

The point we wish to emphasize in this connection, however, is that there appears to be a feeling of resentment on the part of ship captains against the wireless service on board of their ships. They seem to labor under the impression that wireless operators, in the legitimate performance of their duties, are in some way encroaching upon their authority, and they do not take kindly to suggestions from the mere lads usually employed as wireless operators.

There was too much confusion and lack of organized effort in the wireless service in connection with the loss of the steamer. Everybody connected with the affair appeared to be unprepared and on one, even on the "Titanic," seemed to realize that the situation called for action.

But these delinquencies are not devoid of valuable lessons; they show the danger of becoming lax in duty, and the importance of harmony and coöperation between all the departments of a ship organization.

The wireless, if properly used, is an agency for great good, but if abused, can do much harm.

Mr. L. H. Korty, an old time and military telegrapher, formerly and for many years superintendent of telegraph of the Union Pacific Railway, at Omaha, Neb., now retired, writes: "It is always a great pleasure for me to renew my subscription to TELGRAPH AND TELEPHONE AGE."

An Admonition in 1902 Regarding Wireless.*

There was something prophetic, as well as admonitory, in the comment made by Rear-Admiral R. B. Bradford, U. S. N., in his annual report of 1902, as chief of the bureau of equipment, concerning wireless telegraphy. It comes up now with striking significance in view of the difficulties encountered in wireless communication concerning the disaster which sent the "Titanic" to the bottom of the sea. In 1902 the bureau of equipment was negotiating with various wireless companies in an effort to accomplish some arrangement by which there would be adequate control of this means of communication. The greatest difficulty was encountered at every turn. Rear Admiral Bradford called attention to the interference with wireless messages, then so menacing, and pointed out the importance of a governmental control of all wireless transmitting and receiving stations, adding, "It also appears important that this should be done before the vested interests in connection therewith become too great," the bureau then having "especially in mind a large wireless station recently established by a foreign company on Cape Cod."

Admiral Bradford stated, also, in his report: "The bureau is officially informed that foreign countries are exercising careful supervision over the location of wireless stations within their respective territorial limits with the view of having at all times absolute control over them. In time of war, the department will undoubtedly find it necessary to communicate by means of wireless telegraphy with certain receiving stations along the coast. Nothing should be permitted to interfere with the transmission of such messages, nor should it be possible for unauthorized persons to receive them. The only practical method of insuring this result is to secure government control over all wireless telegraph stations along the coast. It is suggested that legislation to this end be requested."

That was ten years ago and nothing has been done, although something was attempted by people who appreciate the necessity of protecting radiocommunication from the interference that would not only impair its value, but, under certain circumstances, would bring great injury and disaster to those in danger. That phase of the situation has appeared in the experience of the lost "Titanic," as it has repeatedly on other less notable occasions.

The bureau of equipment from the first made a diligent effort to obtain legislation which would effect government control of wireless communication. It sought, also, to prevent a monopoly which was a threatening aspect of the early development of the system and Rear Admiral Bradford succeeded in that plan, although he was seriously handicapped by conditions which were persistent and formidable. There has been no lack of advice and warning regarding this menace; but, as usual, it has taken a disaster of overwhelming magnitude to attract attention to the possibilities and the necessities of the situation. Perhaps the recommendation of the chief of the bureau of equipment in 1902 will now gain the attention and receive the support it deserved when Rear Admiral Bradford made it.

Course of Instruction in the Elements of Technical Telegraphy—XVI.

(*Copyrighted.*)

(*Continued from page 312, May 16.*)

[We began in our issue for October 16, 1911, the publication of a course of instruction in technical telegraphy. The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and is divided into chapters, following one another in logical order.

The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases, and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.]

QUESTION PAPER.

(1) What is conductivity?

(2) Why is the resistance of a derived circuit less than if one conductor only were used?

(3) Why is the conductivity of a derived circuit greater than if one conductor only were used?

(4) A derived circuit has three branches of 2, 500, and 800 ohms respectively. What is the fall of potential in the derived circuit when the current in the main circuit is .1 ampere?

(5) How would you find the joint conductivity of two wires in parallel whose resistances are unequal?

(6) How is the joint conductivity of three wires in parallel determined?

(7) (*a*) If a resistance of 150 ohms be connected between the terminals of a 150 ohm relay, what difference will it make to the resistance of the circuit?

(*b*) Would the relay receive more or less current under the above conditions?

(*c*) Why?

(8) A circuit is working between New York and Boston, with a battery of 100 volts at New York end. What is the potential at a point on the line where the resistance on either side is exactly equal?

(9) In the above circuit if the wire be of uniform resistance, and the relay resistance the same at each end, would the point necessarily be at the middle of the line?

(10) Two wires are fed from a gravity battery of 50 volts. The resistance of one wire with instruments is 500 ohms, the resistance of the other and its apparatus is 300 ohms, what is the current strength in each wire?

(11) (*a*) A circuit has a battery of 40 volts and a resistance of 1000 ohms. At a point where 450 ohms resistance has been overcome what is the potential?

(*b*) If the potential has fallen to 20 volts how much resistance has been overcome?

(12) (*a*) Referring to Fig. 3 (see May 1 issue), if the branches are 20, 40 and 60 ohms respectively, and the potential difference between A and B 20 volts, what is the current in each branch?

(*b*) What is the current in the circuit?

(*c*) What is the joint resistance of the branches?

(*d*) What is the resistance to the current between A and B?

(13) It is required to find the resistance of an unmarked relay. The current in the circuit is .02

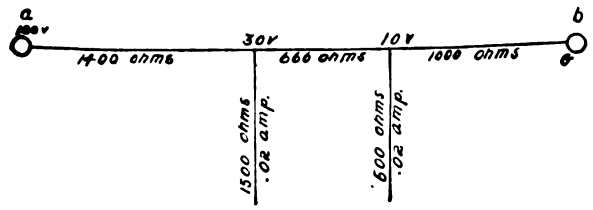

FIG. 4.—DIAGRAM OF MAIN CIRCUIT WITH TWO BRANCHES.

ampere, and the fall of potential between the terminals of the relay as shown by a volt-meter is 3 volts.

(14) Give examples of wires in parallel?

(15) Why is the earth almost a perfect conductor?

(16) In Fig. 4, AB is a main circuit with two branches of 1500 and 500 ohms resistance respectively.

The E. M. F. applied to the circuit at A is 100 volts.

The current in each branch is .02 ampere.

(*a*) If the current in the main line between D and B is .01 ampere, what is the current strength between A and C?

(*b*) Neglecting the resistance of the battery what is the resistance of the entire circuit?

(*c*) What is the resistance of the line and branches between C and B?

(*d*) Why is the potential at C only 30 volts?

(*e*) What is the resistance of the line and branch between D and B?

(*f*) Why is the current in the 1500 ohm branch .02 ampere?

(*g*) If the branch at D be open how will the potential at C be affected?

(*h*) If the branch at C be open how will the potential at D be affected?

Mr. Taft Presses a Button.—The Newark Industrial Exposition at Newark, N. J., was opened May 13 by President Taft, who "pressed a button" at a railroad station in Ohio. He was traveling on a train between Bellaire and Steubenville, Ohio, and the train was stopped in order to let him step into the telegraph office and perform his pressing duty.

Telegraph in Alaska.—The Ruby Telegraph Company, at Ruby, Alaska, has stretched a wire across the Yukon river to connect with the military telegraph line on the opposite side of that stream. Heretofore messages have been carried across the river on boats. The connecting wire is 1000 feet long.

ANSWERS TO QUESTIONS.

[In this department questions on matters of a practical character, and of general interest, will be answered. Questions intended for this department must be signed by the writer's full name—not for publication, but for identity. No attention will be paid to anonymous communications.]

(94) Q. Referring to the article on the KR law on page 215 of your April 1 issue, will you kindly give a reliable method by which the capacity of a wire may be ascertained, using either the new Athearn or the old Western Union quadruplex sets? In other words, how would you proceed to find the value of K in connection with the KR law?

R. S. V.

A. If no other apparatus is available, get a balance as for duplex working on a bridge set. The capacity of the line will approximately equal that of the condensers in the artificial line, when no "kick" is observed on the needle of a sensitive galvanometer, or a mil-ammeter connected across the line and artificial line terminals.

The following method may be adopted when we have not an adjustable condenser available, but have a condenser of known capacity, say K, and a ballistic galvanometer:

(1) Charge the line direct from the battery by means of a key. Then discharge it through the ballistic galvanometer—note the deflection. Call this D. [For this test the line should be insulated, or disconnected, at the point up to which the capacity test is being made.]

(2) Next, charge and discharge a standard condenser in the same manner, using the same battery or dynamo as before. Call the deflection in this case d. Then the capacity of the line equals the capacity of the condenser multiplied by D and divided by d, or,

$$\text{Capacity of line} = \frac{KD}{d}$$

This test works well when the general insulation of the line under test is good. The key should be so connected that the contact is closed, for say five seconds, to charge the line, or the condenser, in each case. The time of charge should be the same in both cases.

(95) Q. Kindly tell me (1) how many ampere-turns there are to a 300-ohm main line relay, assuming that it is working on 45 milliamperes. (2) What size wire and how many thousand feet of it would be necessary to make a relay with the same magnetic strength as a standard 300-ohm relay working on 45 milliamperes, if the new relay was to have 35,000 ohms resistance? I would also like to know (3) the approximate cost of manufacturing one hundred of these relays?

H. H. H.

A. (1) Two coils, each of 4400 turns of No. 32 = 8800 turns. Ampere turns = turns × amperes = 8800 × .045 = 396 ampere turns.

(2) Obviously, as the current is the same as in question 1, the number of turns must be the same, if the number of ampere-turns is to be alike in both cases. Therefore, with the same number of turns the resistance of and consequently the length of each turn must be much greater in the case of a 35,000-ohm instrument than with a 300-ohm one. In the 300-ohm instrument the resistance per

$$\text{turn} = \frac{300}{8800} = .0034 \text{ ohm.}$$

In the 35,000-ohm instrument the resistance per

$$\text{turn would be } \frac{35{,}000}{8800} = 4 \text{ ohms nearly.}$$

Using the same gauge wire, as in the case of the 300-ohm instrument, the length per turn would have to be increased proportionately from .0034 to 4., that is, in proportion to the resistance.

The average length per turn of a 300-ohm relay is .228 foot, therefore the length per turn, using the same gauge for a 35,000 instrument, would be nearly 268 ft., i. e.:

.228 × 35,000 divided by 300 = 266 ft.

The length of No. 35 wire required would, therefore, be 266 × 8800, that is, the length per turn multiplied by the number of turns, equal to 2,340,800 feet.

Using a thinner wire than No. 35, the length could be considerably reduced. As the resistance of three feet of No. 35 wire equals that of one foot of No. 40 wire, the length of the No. 40 wire would be only 780,266 feet. The winding space required to accommodate this amount of No. 40 wire, in 8800 turns, would, however, be so great as to preclude the use of such a design for the main line relay electromagnet.

It must not be lost sight of, too, that to maintain a current of 45 milliamperes in a 35,000-ohm relay, the voltage would have to be increased to nearly 120 times that used with 300-ohm relays.

(3) Relays of this description could be manufactured at a cost of about $5.00 each.

Valuable Books.

"Modern American Telephony in All Its Branches," edited by Arthur Bessey Smith. A very complete and up-to-date work on the subject of telephony. It has over 800 pages and nearly 600 illustrations. Price, $2.00 per copy.

Electrician's Operating and Testing Manual. By H. C. Hortsman and V. H. Tousley.

This work gives practical instructions for the management, operation and testing of the more important electrical devices now in use. It deals principally with electrical machinery and apparatus and contains much information of general value to the student of telegraphy and telephony. It is free from higher mathematics and is written in plain, easily-understood language. Liberally illustrated and substantially bound in flexible leather. Price $1.50 per copy.

These books and any others on electrical and kindred subjects, published in America or in foreign countries, may be obtained of TELEGRAPH AND TELEPHONE AGE, 253 Broadway, New York.

Telephone Train Dispatching.

In our issue dated June 16, 1911, we printed a table giving statistical information as to telephone train dispatching on railroads in the United States and Canada, which showed that at the time it was compiled there were 40,160 miles of track controlled by telephone. For the year previous the record showed a total mileage of 24,831; therefore the gain in mileage in the year 1910-11 over the previous year was 15,329, or slightly over 60 per cent.

Since June 1, 1911, we have recorded in these columns separate installations and extensions of train dispatching circuits aggregating close on to 6,000 miles, and no doubt a closer analysis would bring the actual work done to a higher figure.

Our records show that many of the small railroads throughout the country are adopting the telephone dispatching system, especially in the southern states, and the larger lines are continually making extensions. On April 1 eighteen southern railroads were using the telephone over 7,800 miles of line, on a total of fifty-six circuits equipped with over 1,500 selector way stations.

Telephone dispatching is being so rapidly adopted in every section of the country that a very close record is not possible, under the changing conditions. It is safe to assume, however, that the total railway mileage covered by telephone dispatching at the present time is 46,000.

In our issue dated October 16, 1911, we printed an article by Mr. W. W. Ryder, general superintendent of telegraph, New York Central Lines, on the subject of dispatching of trains by telephone. The author there gives a little historical sketch of the development of telephone dispatching, and then presents some figures taken from the Government report of January 1, 1911, showing the extent to which the principal railroads had adopted, up to that time, this method of dispatching trains. These figures are interesting and are reprinted herewith.

New York Central Lines	3,966
Santa Fe	3,884
Great Northern	3,881
Illinois Central	2,550
Burlington	2,383
Rock Island	2,248
Pennsylvania	2,137
Northern Pacific	1,190
Norfolk & Western	1,066
St. Paul	1,044
Total operated by telephone	24,349

Mr. Ryder sets forth the following advantages of the telephone over the telegraph in train dispatching: (1) The telephone is an aid to the dispatcher in that his work is handled more easily as well as more expeditiously; (2) promptness with which operators respond to their calls; (3) the telephone works better in wet and foggy weather than does the telegraph; (4) it provides means of communication to and from blind sidings, and (5) train and engine men favor the change because it helps them to get over the road more promptly.

The telephone, he says, is also rapidly replacing the telegraph in the handling of way-office messages, it having been found possible to handle from 50 to 75 per cent more business over a way telephone circuit in a given time than is possible with a similar telegraph circuit.

Summarized in a few words, the advantages in the use of the telephone for dispatching and other division work, are that it is quicker, safer and more reliable, more flexible, and in addition makes possible better discipline and co-operation between the dispatcher and operators, as well as providing means for officials who are not familiar with the Morse code to obtain immediate and accurate information in cases of emergency, and thus be in better shape to exercise personal supervision.

In our issues dated February 1 and 16 and March 1 and 16, this year, we published statements from the superintendents of telegraph of various railroads, reviewing their experiences with telephone dispatching on their respective roads, and in every case the record is highly favorable.

The use of the telephone as a means of dispatching and controlling trains was first brought to the attention of the railway telegraph superintendents at the Chicago convention in 1902.

The Typewriter in Press Service.

BY P. V. DE GRAW, FOURTH ASSISTANT POSTMASTER-GENERAL, WASHINGTON, D. C.

Mr. P. V. DeGraw having been requested to prepare an article giving the result of his observation on telegraphic matters during the past thirty years, writes:

"There is not much of interest upon which I might elaborate beyond the introduction within the thirty years of the typewriter as a telegraphic receiver. That innovation, you will recall, was inaugurated by Mr. Walter P. Phillips during his sojourn in Washington as resident agent of the New York Associated Press when I was assisting him.

"I recall very vividly that I had not long before that time been transferred from the telegraphic to the reportorial staff, and that my telegraphic associates were inclined to criticise my hearty support of the order, in the belief that it could not succeed, and I believed entertained a feeling that my change of work prejudiced me in its favor. However, the new departure, while embarrassing to the news service for perhaps a fortnight, proved to be a great boon thereafter, and I think every telegrapher who has accustomed himself to receiving by typewriter will sing the praises of Walter P. Phillips for the firm stand taken by him in its inauguration as a telegraphic receiver."

Mr. B. F. Thompson, telephone inspector, Baltimore & Ohio Railroad Company, Baltimore, Md., writes, "It always gives me pleasure to remit to cover my subscription to TELEGRAPH AND TELEPHONE AGE, for I get value received."

Heman Judson Pettengill.

Mr. H. J. Pettengill, recently elected president of the companies in the Southwestern Bell Telephone System, with headquarters at St. Louis, Mo., was born in Brunswick, Me. The system over which he has jurisdiction is composed of the Bell Telephone Company of Missouri, operating in the eastern half of Missouri; The Missouri and Kansas Telephone Company, operating in Western Missouri and Kansas; the Pioneer Telephone and Telegraph Company, operating in Oklahoma, and The Southwestern Telegraph and Telephone Company, operating in Arkansas and Texas.

The territory in which these companies operate has an area of more than fifty-three thousand square

H. J. PETTENGILL.
President Southwestern Bell Telephone System, St. Louis, Mo.

miles and a population of more than twelve million people, furnishing service to nine hundred and twenty-six thousand telephone subscribers.

Mr. Pettengill is one of the foremost telephone men of the day and stands high in the councils of the American Telephone and Telegraph Company. Like many other leaders in the telephone industry, Mr. Pettengill started business life in the telegraph and occupied positions of prominence while connected with it.

Mr. Pettengill entered the service of the American Telegraph Company in his native town in 1865. Two years later he became manager of the Western Union office at Lewiston, Me., and subsequently, after two or three years' service at Augusta, he entered the Boston office of the same company and remained there for eleven years. In 1881 he was appointed manager of the Boston office of the American Rapid Telegraph Company and in 1883 became superintendent of the Bankers and Merchants Telegraph Company. He later received the appointment of superintendent of the Postal Telegraph-Cable Company at Boston, which position he held until 1899, when he entered the telephone service.

He was elected vice-president of The Southwestern Telegraph and Telephone Company, the Northwestern Telephone Exchange Company, the Wisconsin Telephone Company, the Michigan Telephone Company and the Cleveland Telephone Company, June 1, 1899. December 31, 1904, he was elected president of The Southwestern and Northwestern Telephone Companies, and took up his residence at Minneapolis, Minn., where he remained for about three years, and then resigned the presidency of the Northwestern Company and established his headquarters in Dallas, Tex. While in Dallas, Mr. Pettengill gave his entire time to the Southwestern Company, which has increased its business from 94,889 subscribers' stations on March 1, 1908, to 153,147 subscribers' stations March 1, 1912.

Mr. Pettengill is a thirty-second-degree Mason, Past Commander of Hugh de Payens Commandery, Knights Templars of Melrose, Mass.; past president of the Boston Electric Club and also of the Old Time Telegraphers' Association. He has been chairman of the executive and finance committees of the Commercial Secretaries and Business Men's Association of the State of Texas, which organization is working for the upbuilding and development of the Lone Star State. He is a member of the St. Louis Club and the Noonday Club of St. Louis.

"C. Q. D." and "S. O. S."

The following official explanations of the wireless distress signals "C. Q. D." and "S. O. S." will be of general interest at this time. The signal "C. Q. D." is the Marconi signal of distress, which is only used in cases where ships are disabled and are in danger. "C. Q." is the Marconi call for all stations generally, and is immediately answered by any station receiving it.

The meaning of "C. Q. D." is "All stations danger" and the letters "S. O. S." adopted by the International Wireless Convention convey the same meaning. Rule XVI of the International Wireless Convention is as follows:

Ships in distress shall use the following signal:

" . . . — — — . . . "

repeated at brief intervals.

As soon as a station perceives the signal of distress it shall cease all correspondence and not resume it until after it has made sure that the correspondence to which the call for assistance has given rise is terminated.

In case the ship in distress adds at the end of the series of her calls the call letters of a particular station the answer to the call letters shall be incumbent upon that station alone. If the call for assistance does not specify any particular station, every station perceiving such call shall be bound to answer it.

The best way to keep posted in telegraphic and telephonic progress is to read TELEGRAPH AND TELEPHONE AGE. Subscription price $2 per year.

Testing on Railroad Telephone Circuits.

BY K. W. ENDRES, NEW YORK.

(*Concluded from page 320, May 16.*)

TRANSMITTER BATTERY.

Three dry cells connected in series to give four volts, are required for the testing operator's transmitter battery. They need to be renewed only when the transmission becomes unsatisfactory. The zinc, or negative, pole of the transmitter battery should be connected to the "TB" terminal and the carbon or positive pole should be connected to the "TG" terminal. (Fig. 12.)

HOWLER BATTERY.

This is an auxiliary battery only, and consists of twelve dry cells connected in series to give fifteen volts. It is used only when the howler or "H" key and equipment are furnished, and may be placed with the other dry batteries if found convenient. The zinc and carbon poles of this battery are connected respectively to the terminal marked "4" on the repeating coil and the terminal of the coil winding on the buzzer.

RINGING EQUIPMENT.

If the exchange is not equipped with an interrupter or other source of ringing current, the hand generator on the switchboard may be used as a source of ringing current supply. Provision is also made so that if desired the generator may be added in the testing cabinet itself. This arrangement will be found desirable when the cabinet is located in the terminal or wire chief's room, although in such cases it will be found advisable to connect the terminals mentioned to the interrupter or ringing machine, if any is used.

TELEPHONE LINE FROM SWITCHBOARD.

When the "Tel" key and telephone line from the switchboard to the cabinet is furnished, a telephone set consisting of a ringer and condenser should be used and located near the cabinet. This set may be a No. 127 type and should be connecteded to the "Tel Line," "T" and "R" terminals in the cabinet.

WIRING.

All leads carrying talking current should be twisted pair, and it is suggested that, wherever possible, twisted pair leads be used, for convenience, for other circuits also. No. 19 or 20 B. & S. gauge braided rubber-covered wire will be found most suitable for the leads to the testing cabinet.

METHOD OF OPERATION OF TESTING CABINET.

This test box is designed for making the following tests on magneto lines and may be arranged to make the same tests also on common battery lines.

(a) Talking to subscriber.
(b) Ringing.
(c) Continuity tests.
(d) Tests for short circuits.
(e) Tests for grounds.
(f) Tests for crosses with lines carrying current.
(g) Tests for crosses with other lines.

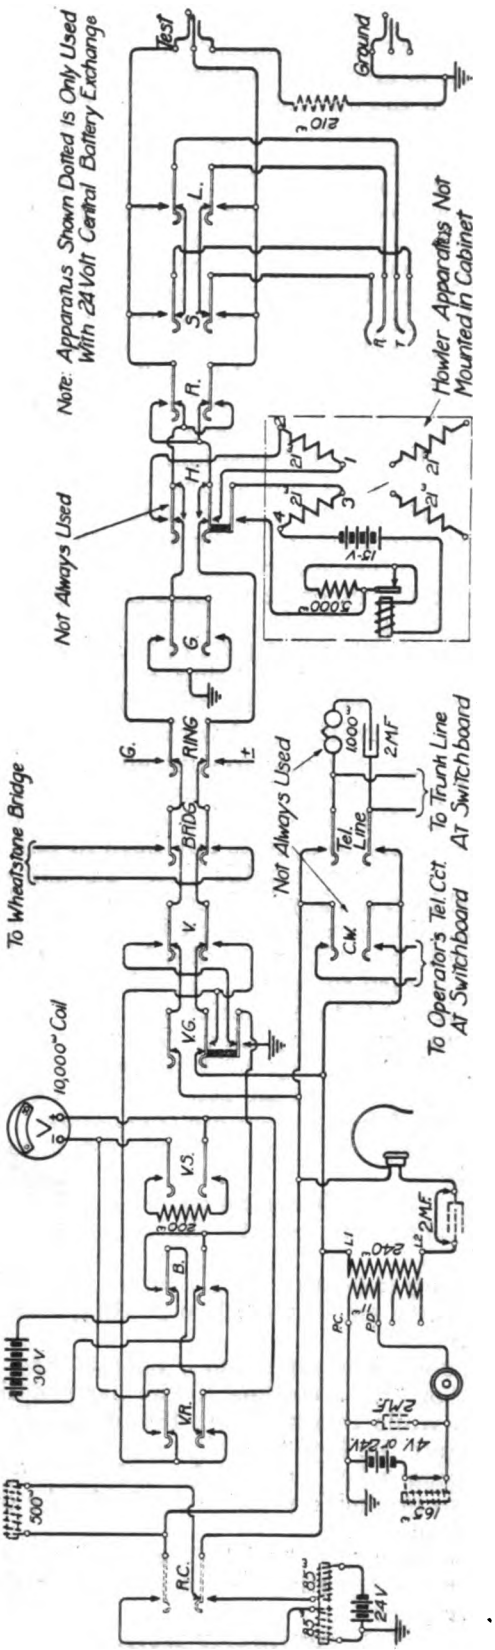

FIG. 12. CIRCUIT OF TESTING CABINET.

Digitized by Google

(h) Location of crosses or grounds by means of Wheatstone bridge.

(j) Ballistic capacity tests.

(k) Howler (when specified).

The set is arranged so that tests can be made either from the switchboard or from the distributing frame. When testing a line from the distributing frame the heat coils are removed and the No. 128 plug inserted in place of them. Key "L" is operated for testing the line and key "S" for testing the switchboard wiring. When neither key is operated the line is connected to the switchboard. When testing a line at the distributing frame the test plug must not be left in any line.

Tests are made through the switchboard by inserting the plug marked "Test" in the jack of the line to be tested. When testing a line through the switchboard, keys "S" and "L" must not be in the operated position. In cases where the whole face of the switchboard cannot be reached with the test plug, it is necessary to use test lines terminating in plugs at one end, and jacks at the other for extending the test cord to positions that cannot be reached directly.

Tests through the switchboard are in general more conveniently made than tests at the distributing frame, the latter being most frequently used when it is thought that there may be trouble in the switchboard wiring or apparatus.

(a) TALKING TO SUBSCRIBER.

(1) Magneto Line. The telephone set is normally connected to the testing circuit, so that it is not necessary to operate any keys to talk to a telephone set on a metallic line. To talk on a grounded line, the key "G" must be operated and in case the line wire is connected to the tip spring of the jack, key, "R" must also be operated. It is not necessary to operate these keys, if the tip is grounded at the distributing frame.

(2) Common Battery Line. To talk to a telephone set the "RC" key must be operated to supply talking battery to the set. This talking battery and the telephone set are completely cut off from the line when any of the test keys are operated.

(b) RINGING.

1. To ring single-party lines, operate key "Ring."

2. To ring two-party lines, operate key "Ring" for first party and keys "R" and "Ring" for second party.

3. To ring four-party lines, operate key "1," "2," "3," or "4," according to the party desired, and then while this key is in the operated position, operate the key "Ring."

4. To ring a bell bridged from the tip side of the line to ground key "R" must be in the operated position.

NOTE.—Keys "1," "2," "3" and "4" must be in their normal position when ringing single or two-party lines.

(c) CONTINUITY TESTS.

To test the continuity of the metallic line, operate key "V." If the line is continuous the voltmeter will show a deflection. There will be no deflection if the line is open. To test a grounded line, operate key "VG" instead of "V." Key "R" must also be operated if the tip of the jack is connected to the line wire. No deflection will be shown if condensers are used in series with the ringers at the subscribers' sets, which is the case with common battery sets. In this case the test is made by operating key "V" or "VG" as described and while it is in the operated position, operating key "B" several times. This will cause momentary deflections, due to the charge and discharge of the condenser.

(d) TEST FOR SHORT CIRCUITS.

Tests for short circuits are made by observing the deflection when the key "V" is operated. The smaller the resistance of the short-circuited line, the greater the deflection will be. In all cases the voltmeter reading bears the same ratio to the voltmeter resistance that the difference between this reading and the testing battery voltage bears to the line resistance. The line resistance may be found by dividing the difference between the testing battery voltage and the voltmeter reading by the voltmeter reading and multiplying the result by the resistance of the voltmeter. This resistance in the case of this set is 10,000 ohms.

For example, if the testing battery is at 30 volts and a reading of 25 volts is found on testing a line, the resistance is

$$\frac{30-25}{25} \times 10{,}000 = 2{,}000 \text{ ohms.}$$

By operating the key "VS" the voltmeter is shunted by a resistance of 200 ohms, so that the combined resistance is 196 ohms. With this key operated the deflection with any given line resistance is much smaller, and it is much easier to calculate the resistance.

For example, with a battery voltage of 30 and a reading of 10 volts on a test, the resistance is

$$\frac{30-10}{10} \times 196 = 392 \text{ ohms.}$$

By measuring the resistance in this manner it is easy to distinguish between a short circuit and the effect of one or more bells bridged across the line without condensers.

It is a convenience to short circuit an unused jack in the switchboard for measuring the voltage of the testing battery. The potential is measured by plugging into this jack with the testing cord and operating key "V." The condition of the battery may then be tested by operating both key "V" and key "VS." If the voltage reading falls more than a few volts below that noted when using key "V" only and if the voltage tends to fall while the keys are operated, the batteries are in poor condition and should be replaced.

Digitized by Google

(e) TESTS FOR GROUNDS.

To test for a ground on the ring or sleeve side of the line, operate key "VG." To test for a ground on the tip side operate keys "VG" and "R." The voltmeter should show no deflection or at most a small one if the line is clear, except in the case of grounded lines and party lines where the bells are rung with a ground return, without condensers in series with the ringers. The resistance in this case may be measured as explained under "Tests for short circuits."

(f) TESTS FOR CROSSES WITH LINES CARRYING CURRENT.

Tests for crosses with lines carrying current, such as telegraph lines or common battery telephone lines, are made in the same manner as tests for grounds except that key "B" is operated as well as "VG" and "R." If the needle moves backward when "B" is operated, operate "VR," which will reverse the voltmeter connections. Great care should be used in making this test, as there is danger of injuring the voltmeter if the potential of the foreign line is much in excess of 30 volts.

(g) TESTS FOR CROSSES WITH OTHER LINES.

To test for a cross between two lines, ground one of them by plugging into it with the plug marked "Ground," and test the other for grounds as previously explained. The line tested must be free from grounds for this test to be satisfactory.

(h) LOCATION OF CROSSES OR GROUNDS BY MEANS OF WHEATSTONE BRIDGE.

By operating the key "BRDG" the line under test is connected to the binding posts "BRDG," which should be wired to the line or "X" terminals of the bridge used. No instructions can be given here for tests of this kind, as the methods differ with different types of bridges. With the bridge the location of crosses and grounds can be accurately determined.

The resistance of a short-circuited line may be measured much more accurately by the bridge than by the voltmeter. The connection of the line to the bridge may be reversed by operating key "R."

(j) BALLISTIC CAPACITY TESTS.

A ballistic test may be used for roughly determining the capacity between the tip and ring sides of a line. Operate key "V" and then operate key "B" several times, noting the "throw" of the voltmeter needle. The greater the "throw" the greater is the capacity. If the voltmeter is not shunted the capacity is proportional to the deflection. To measure the capacity between the ring side of the line and ground proceed in a similar manner, but use key "VG" in place of key "V." To measure the capacity between the tip side of the line and ground use keys "VG" and "R" in place of key "V." This test may be used for locating the distance to a break by comparing the capacity of the line with its normal capacity which has been previously determined and recorded. In making these tests on metallic lines key "R" may be used to advantage instead of key "B" for charging and discharging the line. On operating and restoring key "B" the voltmeter deflections are in opposite directions, while with key "R" they are always in the same direction and of twice the magnitude. Key "R," however, cannot be used in this way for measuring the capacity between one side of the line and ground.

(k) HOWLER.

The howler may be connected to a line by operating the howler key if furnished. This closes both the primary and secondary circuits, starting the buzzer, which is used as an interrupter, and connecting the high-frequency alternating current produced in the secondary, to line. In cases where the subscriber has left his receiver off the switchhook and cannot, therefore, be called by ringing, the howler is employed to make a noise in his receiver to attract his attention.

SUGGESTIONS CONCERNING THE USE OF THE TESTING CABINET.

1. It is suggested that when grounded lines are used the circuits be metallic between the switchboard and the protector frame, and that the "tip" side of the line be grounded on the outside of the fuses; that is, the circuit will be metallic between the fuses and the switchboard.

The "tip and ring" methods of designating the two sides of the line is derived from the plug used on the switchboard. By examining this plug, one will find that it is composed of two conductors which are separated by an insulating strip. One of the cord conductors terminates on the tip of the plug and the other on the ring. This method of distinction is applied to the line. That side of the line which is connected to the short spring of the jack is called the "tip" side of the line; that is, the shorter spring comes in contact with the tip of the plug. That side of the line which is connected to the long spring of the jack is called the "ring" side of the line, the longer spring coming in contact with the ring of the plug. On a common battery switchboard it is customary to use a three-wire line and cord circuit, the third wire being designated as a sleeve.

2. The normal resistance and normal capacity of each line should be accurately recorded in an indexed card file. Any deviation from the recorded data may be taken as an indication of trouble.

3. It is suggested that each morning all of the line circuits be tested. In this way small troubles may be located and cleared before they develop into serious interruptions of the service.

4. In making measurements on lines having several bridged ringers it must be kept in mind that the loop resistance of any line decreases with the addition of more ringers.

5. When a lineman is working upon a line circuit, after he has located and cleared any one "piece of trouble" it is always advisable for him to call up the operator and have a test made upon

Digitized by Google

the line circuit to see if all the trouble has been removed. This co-operation between the operator and lineman will greatly facilitate the clearing of trouble and prevent making repeated trips over the line circuits.

6. When a receiver is "off the hook" at any station there is a low resistance shunt (about 70 ohms) across the line.

7. By disconnecting all of the telephone sets from the line (this may be done by temporarily disconnecting the line wire from the binding posts) and placing a "dead short circuit" at the end of the line, the loop resistance of the line can be measured; that is, the resistance of the two line wires.

By consulting the following table of resistances, it can be ascertained if faulty joints are in the circuit. Theoretically, the joints are supposed to have practically no resistance, but owing to the corrosive action of the atmosphere, the resistance may be increased. This has a tendency to unbalance the telephone line, producing noises and distorting the transmission. By changing the location of the temporary "short circuit" the approximate location of the faulty joint may be ascertained.

PROPERTIES OF HARD DRAWN BARE COPPER WIRE.

	Weight per mile in lbs.	Resistance per mile in ohms.
No. 8, B. & S.	264	3.3
No. 9, B. & S.	209	4.1
No. 10, B. & S.	166	5.2
No. 12, B. & S. (a)..	104.5	8.3

(a) No. 14, N. B. S., is practically the same size as No. 12, B. & S.

PROPERTIES OF GALVANIZED IRON WIRE OF B. B. GRADE.

	Weight per mile in lbs.	Resistance per mile of single wire in ohms.
No. 8, B. W. G.	378	14.6
No. 9, B. W. G.	305	18.1
No. 10, B. W. G.	250	22.1
No. 12, B. W. G.	165	33.3
No. 14, B. W. G.	96	57.5

NOTE.—The above calculation of weights and resistances is correct for a temperature of 68 deg. F. At a higher temperature the resistance will be higher, and a lower temperature the resistance will be lower.

The First Leased Telegraph Lines for the Transmission of Press Dispatches.

To the late James C. Hueston, an old telegrapher, aided and abetted by Walter P. Phillips, who succeeded Mr. Hueston as assistant general manager of the New York Associated Press, is due the idea of leased telegraph lines for the convenience and more rapid handling of press matter, replacing the old method of filing "copy" with the telegraph company, and insuring greater dispatch and accuracy.

It was in December, 1874, that Mr. Phillips, then one of the editors of the reports sent to New York State and the Pacific Coast, became actively interested in the exploitation of a special wire that was being leased by the New York Associated Press between New York and Washington, with branches at Philadelphia and Baltimore. To add to the efficiency of this circuit Mr. Phillips was given carte blanche by Mr. Hueston, who was the assistant general manager of the press association, to secure the finest talent in the country, and he succeeded in engaging for this exacting service Messrs. P. V. DeGraw (now fourth assistant postmaster general of the U. S.), and E. C. Boileau, who were assigned to the New York office; W. H. C. Hargrave and W. N. Gove at Philadelphia; T. J. Bishop and H. A. Wells at Baltimore, and F. N. Bassett and W. G. Jones at Washington. These men became known all over the country as the "original leased wire eight."

The speed at which this wire was worked never had been reached before, nor has it been exceeded since except through mechanical contrivances. The daily average per man before the adoption of typewriters was about 14,000 words; 28,000 words day and night, or about twenty-nine words per minute between the hours of 10 a. m. and 2 a. m. within each twenty-four hours. This was hard, exacting work, as the telegraphers in some of the offices were compelled to make eighteen to thirty manifold copies—which was bound to tell upon the men sooner or later. Mr. Phillips, after much experimentation, found relief in a system of abbreviated telegraphy, which he subsequently copyrighted, and which is in general use today, in handling press matter. It is known as the Phillips Code, or Steno-Telegraphy, and while it adds to the efficiency of a wire more than fifty per cent., being used in connection with the typewriter, at the same time relieves the strain on the operator in marked degree.

This original leased wire was the nucleus of the present extensive system employed by nearly all the larger newspapers in the country, the practice having become general rather than exceptional, and its utility and necessity firmly established.

The Telegraph in Morocco.—A system of telegraphs is being established in Morocco, and it is stated that the Sultan is about to grant a concession for the erection and working of telephone exchanges giving communication between the principal towns.

Singing Messengers in Boston.—Messenger boys at the Boston Chamber of Commerce practice a unique method of finding members on the floor when they have telegrams to deliver. The boys sing the address so that all may hear, and one little fellow with fine feeling warbles like a lark till he finds his man.

The Progress of Wireless Telegraphy.

In his lecture before the New York Electrical Society, April 17, Mr. Guglielmo Marconi discussed the present state of the wireless art, after briefly reviewing the early work which led up to the discovery by Hertz in 1887 of the propagation of ether waves.

Referring to the capacity of aerials he said:

When the key of the transmitter is pressed the high-tension current is allowed to charge the vertical wire, or aerial, which when discharging causes a rapid succession of sparks to pass across the spark-gap. The sudden release caused by the spark discharge causes a large amount of energy to be thrown off into space in the form of a displacement wave in the ether; and, as a consequence, the vertical wire becomes a radiator of electric waves.

The rapid electrical oscillations in the wire produce two effects in external space, called respectively electric and magnetic force. In the case of a simple vertical air wire the magnetic force is distributed along certain looped lines in the plane of the wire. As the currents in the air wire reverse their direction, the magnetic and electric force in space also reverse, but not everywhere at the same moment. The magnetic and electric forces are states of the ether, and in virtue of the inertia or elasticity of the medium they are propagated from point to point with the velocity of light.

The receiver consists of an air wire connected to ground through some device which makes it possible to detect the effects of the minute currents induced in the receiver by the action of the waves transmitted to it by the sender.

Although the transmitter referred to has extraordinary efficiency, in the matter of radiation of electrical energy, it has numerous drawbacks. The electrical capacity of the system is very small, with the result that the small amount of energy in the aerial is thrown into space in an exceedingly short period of time. In other words, the energy, instead of giving rise to a train of waves is dissipated after a few oscillations, and, consequently, anything approaching good tuning between the transmitter and the receiver is found to be unobtainable in practice.

With the new disk transmitters which are utilized in long-distance stations it is possible by interrupting or quenching the spark in the condenser circuit at the right moment to open the primary circuit and thereby render it incapable of oscillating by means of energy which would otherwise be retransferred to it by the antenna of the radiating circuit, and in this manner prevent the interaction of the two circuits, which is the condition causing the production of two waves and the consequent waste of energy.

It is possible to couple to one sending conductor several differently tuned transmitters, and to a receiving wire a number of corresponding receivers, each individual receiver responding only to the radiations of the transmitter with which it is in resonance.

A result of scientific interest which was first noticed by Marconi on the steamship "Philadelphia" in 1902, and which still remains a most important factor in long-distance space telegraphy, is the detrimental effect produced by daylight on the propagation of electric waves over great distances. The generally accepted hypothesis of the cause of this absorption of electric waves in sunlight is founded on the belief that the absorption is due to the ionization of the gaseous molecules of the air by ultra-violet light obtained from the sun. It is probable that that portion of the earth's atmosphere which is facing the sun will contain more ions, or electrons, than that portion which is in darkness, and therefore the illuminated and ionized air will absorb some of the energy of the electric waves.

The wave-length of the oscillations employed has much to do with this interesting phenomenon, long waves being subject to the effect of daylight to a very much less degree than are short waves; indeed, in some transatlantic experiments, in which waves about 8000 meters were used, the energy received by day at the distant receiving station was usually greater than that obtained by night.

The fact remains, however, that for comparatively short waves such as are used for ship communication clear sunlight and blue skies, though transparent to light, act as a kind of fog to these waves. Hence the weather conditions prevailing in England, wintry fogs and dull skies, are usually suitable for wireless telegraphy.

Recent observations reveal the interesting fact that the effects vary greatly with the direction in which the transmission is taking place, the results obtained when transmitting in a northerly and southerly direction being often altogether different from those observed in an easterly and westerly one. In regard to moderate power stations such as are employed on ships, and which use wave-lengths of 300 meters and 600 meters, the distance over which communication can be effected during daytime is generally about the same whatever the bearing of the ships to each other or to the land stations, while at night interesting and apparently curious results are obtained. Ships over 1000 miles away off the south of Spain or around the coast of Italy can almost always communicate during the hours of darkness with the post office stations situated on the coasts of England and Ireland, while the same ships when at a similar distance on the Atlantic from the westward of these islands and on the usual track between England and America can hardly ever communicate with these shore stations unless by means of specially powerful instruments.

It is also to be noticed that in order to reach ships in the Mediterranean the electric waves have to pass over a large portion of Europe and in many cases the Alps. Such long stretches of

Digitized by Google

land, especially when including very high mountains, constitute an insurmountable barrier to the propagation of short waves during daytime. Although no such obstacles lie between the English and Irish stations and ships in the North Atlantic en route for North America, a night transmission of 1000 miles is there of exceptionally rare occurrence.

Although high power stations are now used for communicating across the Atlantic Ocean and messages can be sent by day as well as by night, there still exist periods of almost regular daily occurrence during which the strength of the received signals is at a minimum. Thus in the morning and evening, when in consequence of the difference in longitude, daylight or darkness extends only part of the way across the ocean, the received signals are at their weakest. It would almost appear as if electric waves in passing from dark space to illuminated space and vice versa are reflected and refracted in such a manner as to be diverted from the normal path. Later results seem to indicate that it is unlikely that difficulty would be experienced in telegraphing over equal distances north and south on about the same meridian, as in this case the passage from daylight to darkness would occur more rapidly over the whole distance between the two stations.

One of the objections made against wireless telegraphy is in regard to the possbility of interference between various stations and the confusion likely to arise when a number of stations are simultaneously operated in the vicinity of each other. Although this confusion does rarely arise in practice with proper up-to-date stations and apparatus, yet even with the old instruments when it did occur it was not by any means such a serious matter as generally appeared to the imagination of the public. In most countries the operation of wireless-telegraph stations, in regard to ship and shore communication, is subject to judicious rules tending to prevent mutual interference, and America now intends to promulgate regulations which should greatly increase the effectiveness of wireless working. However, there is a danger of governments hampering the development of this new art by the imposition of too many rules and regulations. Moreover, in the case of wireless telegraphy it is often an advantage that any station should be able to pick up emergency messages.

At present one of the most practical methods of isolating any particular receiver so as to make it sensitive only to signals coming from a certain station is to make use of the principal of resonance and where possible to take advantage of directive methods. It is possible to cause a change of even less than one-half of 1 per cent. in the wave-length of the received waves to cease to actuate the receiver. This means that one can distinguish between two waves 1005 feet or 1010 feet in length respectively, and that the receiver may be tuned to respond to one and not to the other.

Improvements in Gell Perforators.

Some difficulty having been experienced with the older form of Gell perforators in consequence of the excessive current consumption, says the *Postoffice Electrical Engineers' Journal,* of London, it has been found necessary to reduce the power absorbed from 200 to 100 watts. In the newer forms Mr. Gell has effected this reduction by the use of coil and plunger electro-magnets, in place of teams of iron-cored electro-magnets with pivotted armature.

The older forms are being converted at the postoffice factory, and very efficient results are being obtained from a form of coil specially designed by Mr. Mansbridge for the special requirements. This electro-magnet is also of the coil and plunger type, but it differs from that used by Mr. Gell in that it is a single coil instead of a pair, and is iron-clad. The construction is such that the magnetic circuit contains only a single air-gap, and the plunger, which is one inch in diameter, projects into the coil in such a way that when the coil is excited the plunger is very strongly attracted downwards, so as to bridge over the air-gap and complete the magnetic circuit. The stroke of the plunger may be anything that is desired. To obtain a long stroke the electro-magnet is constructed with its interior (hollow) poles one inch or more apart, while for a shorter stroke they may be only half an inch or less apart.

An incidental advantage of this type of electro-magnet is that it affords a cushioning effect for the plunger, since when the plunger has by its movement completed the magnetic circuit, the pull upon it automatically disappears. Hence when used on the punching side the motion of the plunger has not to be checked by any buffer or stop, and in consequence a better mechanical effect is produced.

Mr. William Maver jr., the eminent electrical engineer, of New York, in renewing his subscription for another year, writes: "TELEGRAPH AND TELEPHONE AGE is one of the few papers that I always read from beginning to end, and I would not be without it for much more than the subscription price. For, besides the interesting technical information relating to telegraphy and telephony with which it abounds, it is almost the only means by which those not actively in telegraph work are kept informed as to the present whereabouts of old friends and also, alas too often, as to their departure to that bourne from which no one e'er returns."

Mr. M. W. Jones, acting train master of the Guayaquil and Quito Railroad, Huigra, Ecuador, writes: "I enclose herewith $3.00 to renew my subscription to the AGE. I could not get along without it here in this far-away country. It is the only paper which properly keeps me in touch with the doings of my many friends and old associations in the United States."

Western Union Pensions.

The pension committee of the Western Union Telegraph Company has drafted the following regulations governing pensions:

This provisional plan shall take effect on the first day of July, 1912; subject, however, to the following reservations and conditions, to wit:

That all pensions hereunder are made at the discretion of and during the pleasure of the board of directors of the executive committee only and are not to be deemed in any way continuing obligations of the company, nor shall any rights therein or to a continuance thereof vest in the recipients beyond the pleasure of the board. Power to change the same in any and all respects or to discontinue the same entirely at the discretion of the board at any time being hereby expressly reserved.

It is also provided that all pensions under this plan be made at and only upon the recommendation of the pension committee, and that no pension shall exceed the rate of $100 per month, except upon special authorization thereof by the executive committee of the board of directors.

The plan applies only to those in the service of the company or its absorbed companies and who have been in such service for twenty or more years immediately preceding the dates of applications for their retirement.

All such employes who attain or shall have attained the age of seventy years shall be retired on pension upon proper recommendations—the retirements to be effective on the dates approved by the executive committee.

All such employes who have become permanently incapacitated for service through no fault of their own may be retired on pension on proper recommendations on such dates as may be designated by the executive committee.

Continuous service shall be regarded as that within which there has been no break of greater duration than one year. If a break of more than one year has occurred the time is to be computed from the date service was resumed and previous service shall not be counted in determining the amount of the pension.

Leaves of absence, temporary lay-offs, etc., not exceeding one year shall not be considered breaks in continuity of service, but all time out of the service shall be deducted from the pension period.

Discontinuance of regular work without permission for any other reason than sickness or accident shall be deemed sufficient cause for the forfeiture of all benefits accruing under this plan.

In the case of employes originally in the service of absorbed companies the dates of employment shall be reckoned from the dates of entering the service of the absorbed companies.

Pension allowances shall be paid monthly during the life of the beneficiaries or until discontinued by order of the executive committee. No assignments of pensions shall be permitted.

No employe will be permitted to receive a pension and at the same time draw a salary or other compensation from the company.

When an application is based on the ground that the employe has become permanently incapacitated it should be accompanied by a medical certificate which must be certified to by the superintendent or head of department.

Every application for a pension must be accompanied by a letter from the superintendent or head of departments stating the facts in the case with recommendation. A copy of form 2878 properly filled out must accompany each application.

If any employe in receipt of a pension by reason of having been retired on account of illness or incapacity for work shall recover so as to be competent to resume the discharge of the duties of the office or position held by him at the time of his retirement the company may require him to again take up the same and during the period of such further service no payment shall be made to the employe by way of pension. If any employe shall decline to re-enter the service when thus required his right to a pension shall cease.

Any employe in receipt of a pension shall be at liberty to engage in any outside occupation, but if he shall enter upon any employment or engage in any business or undertaking which in the opinion of the executive committee is or may become prejudicial to the interests of the company he shall thereupon cease to have any rights or claim to any pension or in respect thereof.

The right of the company to discharge any employe shall not be in any way influenced by these provisions and all claim to or interest in the pension plan may be forfeited by such discharge.

Applications for pensions should be addressed to the superintendents or heads of departments and should be referred for consideration through the regular channels.

[The rates of pensions were given in our issue dated April 16.]

Liége Electrical Show.—An electrical exhibition is to be held in Liege, Belgium, in 1914, under the auspices of the Association of Electrical Engineers and the Montefiore Institute of Technology. Prizes will be awarded for the most meritorious electrical inventions. Mr. G. L'Hoest, 31 rue Saint Gilles, Liege, is general secretary.

Mr. W. A. Neill, district plant superintendent, Western Union Telegraph Company, at Atlanta, Ga., in renewing his subscription for another year, writes: "I always take great pleasure in recommending your publication, not only for its interesting reading matter, but as being a medium of instruction relating to telegraph and telephone matters, and take pleasure in advancing your interests and encouraging possible subscribers."

Multiplex Telegraphy in the Past Thirty Years.

BY PATRICK B. DELANY, NANTUCKET, MASS.

To my view the most important happenings in telegraphy since your paper began are a disposition to realize the full capacity of a wire for delivering telegraph signals, and that there is at last a scopeful mind managing electrical communication.

Until recently the telegraph was thought to have been finished where it was born, "over on the Jersey side," but a descendant of one of the dot-and-dash designers seems to have taken a different view.

Not much has been done to improve Morse telegraphy in these thirty years. Synchronous multiplexes have come and gone, mainly on account of underground wires and induction between overhead ones.

The quadruplex is not as useful as it was thirty years ago. Polar duplex with typewriting machines and auto-dot transmitters mark the real advances in Morse telegraphy. Printers of great ingenuity and some utility have been and are still being tried out, but the highest development in this line thus far gives me no warrant for changing my opinion, always held and frequently expressed, that the most efficient Morse or printing telegraph is the polar duplex manned with first-class operators, and now, with auto-dot keys, this belief is better grounded than ever.

The change of title for your paper to TELEGRAPH AND TELEPHONE AGE marked the new era of appreciation of what the telegraph should be. The old ten-word message idea for stocks or death was dropped as the aim and limitation of the telegraph. All kinds of communication and correspondence was opened up to the public in the night letter and day letter telegrams and thousands of branch telegraph offices established telephonically, all over the country. The old branch telegraph office idea, typical of stagnation, except in contending for circuit, is being brushed away for the ever ready and accessible telephone dictation service.

People are wondering why these things were not done long ago, as they might have been? The reason is simple. No one in authority appreciated the necessity for progress in telegraphy. They were told thirty years ago and often enough since, the Lord knows, but small minds were in control, and a suggestion of improvement was *lèse majesté*.

There is much more in store for telegraphy in the next five years than shown in developments of the past sixty. Even your paper, since the era of enlightenment has manifested itself in high places, seems to have caught a spirit of broader vigilance for improvements in telegraphy and telephony than was possible in the atmosphere of the old regime.

The telegraph letters of the future will wind up with "Haven't time to write."

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. "Electrical Instruments and Testing," by Norman H. Schneider, with chapters on testing wires and cables and locating faults, by Jesse Hargrave, a well-known and capable electrical engineer, is now being covered in this department. These subjects will no doubt prove of great interest to students, as they are timely and important, and each student should have a copy of the book at hand in order to follow intelligently the study of the subjects under consideration.]

What is a standard cell of battery?

What is such a cell used for?

Is it necessary that a standard cell should deliver a large current?

Why is a thermometer included in the containing case of a standard cell?

Under what circumstances may a Daniell or copper-sulphate cell be used as a standard?

For very accurate work what two makes of cells are necessary?

What are the elements of the Clark cell, and of what metal are the electrodes made?

What is the electromotive force of this cell at a temperature of 15 deg. C.?

Of what substances are the electrodes of the Weston cell composed?

What is the electromotive force of the Weston cell?

What is a voltmeter?

How is a voltmeter connected to the circuit to be measured?

Is the resistance of a voltmeter high or low?

Is the resistance of a voltmeter fixed or variable?

How is the current flowing through a voltmeter varied?

What would be the effect on a current of increasing the e. m. f.?

What would be the effect of decreasing the e. m. f.?

How do these variations in the e. m. f. affect the voltmeter indicating-pointer?

Mr. Van Devender's First Experience with Beautiful Snow.

Mr. H. Van Devender, commercial superintendent of the Western Union Telegraph Company in New Orleans, loves the climate of New Orleans in the summer time. He fairly dotes on the delightful heat that permeates the atmosphere on a sultry evening, when there is not a breeze stirring, and a concert of mosquitoes makes music in his ears.

'Twas not ever thus with Mr. Van Devender, however, says the *New Orleans Daily States.* He has not always been such a strenuous champion of our summer climate. He has not always extolled the exquisite joy of the sun's rays, nor has he always luxuriated in perspiration at the boiling point. In fact, it was only quite recently that he became a convert to this climate, in which he now hopes to dwell on and on forever.

Mr. Van Devenders' transformation from the state of one who endures the climate of New Orleans to the state of one who hopes he may never be separated from it again took place while he was en route to a recent convention of Western Union traffic chiefs in Denver, Col. It happened in this wise. He heard some fellow passengers remark that it was snowing heavily. Snow has always been so scarce in New Orleans that it melted before Mr. Van Devender arose from his slumbers, and he was therefore very anxious to see what it looked like. In fact, his desire was so strong that he encased himself in his bath robe and a pair of slippers and stepped out quietly and unobtrusively on the rear vestibule of his car. There he remained for some time—and a great deal longer than he had intended to remain.

The reason Mr. Van Devender remained on the rear vestibule longer than he had anticipated, and certainly longer than his light vesture warranted, was due entirely to the perversity of the vestibule door, which he found locked when he was ready to go back inside. It was a very disagreeable thing for the door to do—in view of the fact that the snow had chilled the atmosphere and that Mr. Van Devender was not prepared for the occasion. Had he known that the door would be locked behind him, he would at least have brought along an extra blanket or a little something to warm him up—inside. He was not at all accustomed to such climate as that through which he passed while trying to effect an entrance into the car from the vestibule. They never have anything like it in New Orleans, and Mr. Van Devender felt justified in indulging in a few remarks that would have warmed up his immediate vicinity, but for the fact that the train was traveling too fast. He regretted more than anything else that he did not have on two bath robes instead of one.

There was an electric doorbell, and Mr. Van Devender got a little satisfaction out of that, in the hope that it would attract the porter's attention. But the porter failed to respond to Mr. Van Devender's particular code. It continued to snow, and Mr. Van Devender began to suspect that there was an iceberg tied up somewhere in the neighborhood. He had never heard of so much snow in all his life, except when Dr. Cook returned without the North Pole. He got so cold that he made very little impression on the electric button, and finally gave it up. In about an hour they rescued him from the platform. He was almost delirious, and wanted to know when he would get back to New Orleans. Now that he is back, he hopes to remain here for some time to come. There is nothing like the climate of New Orleans for keeps, he says.

A Damper for the Prevention of Telephone Disturbances.—A Swedish engineer, Mr. Saxenberg, has invented an apparatus to reduce or prevent buzzing and all extraneous noises in the telephone. The apparatus consists of a kind of adjustable leak resistance for extra currents on the line in the shape of two columns of water, which are connected with each other and the earth at one end, while the other ends are coupled to the telephone wires. One of these devices is to be inserted at each end of the line, near the telephone apparatus, so as to enable the user of the telephone to reach it, and, by adjusting the one or the other electrode up or down, to cause the buzzing to disappear. By means of its resistance, which is non-inductive, the damper conducts to earth all static charges or induced currents, which take this path in preference to the inductive circuit through the telephone. At the same time, it gives an excellent protection against discharges of electricity from the atmosphere. As both the electrodes can be regulated and the resistances at the poles can thus be varied quite independently of each other, it also becomes possible to compensate for various leakages which may occur in the line. The leakage and the induction vary according to the weather and the atmospheric conditions, and a readjustment of the apparatus accordingly is often necessary so as to obtain the greatest possible "buzz-damping" effect. The apparatus has been tested on the Vesteraas-Traangfors line, which was previously nearly useless, and the improvement was astonishing. The apparatus has been brought into the market by the Allmäna Svenska Elektriska.

Alternating Current Telegraphy.—The *Elektrotechnik und Maschinenbau,* a German electrical and mechanical paper, recently published a long illustrated article by Mr. Béla Gáti, manager Royal Hungarian Telegraph and Telephone Experiment Station, Budapest, Hungary, entitled "Will the Signal be Lengthened in Alternating-Current Telegraphy?" Mr. Gáti has given this subject much attention and investigation.

Mr. W. I. Capen, fourth vice-president of the Postal Telegraph-Cable Company, New York, in renewing his subscription, writes: "I have had the pleasure of paying you for a good many years' subscription to the AGE and do not now propose to give up reading your excellent publication just because you stamped the issue received today 'subscription expired.' The enclosed check is forwarded with all the old-time pleasure mentioned."

CONSERVATION TALKS—VIII.

BY P. KERR HIGGINS, OKLAHOMA CITY, OKLAHOMA.

Functional Organization.

The writer has always been in favor of the idea and purpose of the functional organization, as applied to public utilities, more especially in the telephone business. It has therefore been a pleasure to study its development and see how fully it would meet the demands of the hour. So far as the writer has observed, very few faults can be found with the scheme.

When central energy systems first came into use, everyone tried his best to find fault with it, and among other criticisms was the one that it enforced a higher maintenance cost and more expert help. This criticism was true, but proved to be an argument in its favor, rather than against it.

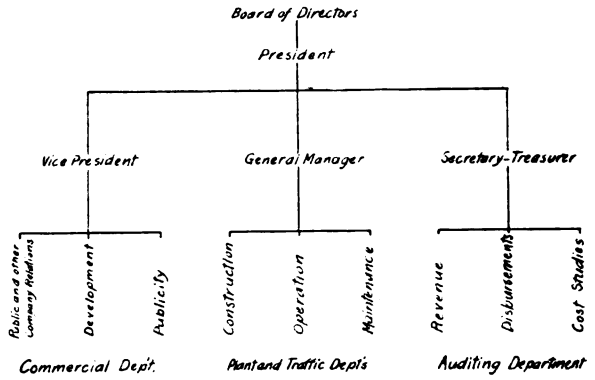
When the territorial scheme of organization was abandoned to be replaced by the functional or three-column plan the same thing happened, and the latter was everywhere criticised because it was built on a foundation of coöperation and coördination, and that only those familiar with these methods could survive its introduction. This very criticism has been the one thing which would justify its continuation. Necessity is the mother of new effort, and so employes finding they must work with and for each other, have not been slow to cultivate the new essential coöperation. As a result we find that the disposition of our best employes is undergoing a change for the better, and since they are not now required to follow the details of every phase of the telephone business, they are becoming more and more expert along the special line of their choice, hence the efficiency along all lines is gradually being advanced and employes are much more contented with their every-day duties than before.

In the course of the writer's observation and study along these lines it occurred to him that there was one link in the organization which did not seem to fit well into the rest of the chain.

It seemed as though the commercial department was called upon to do work which in reality did not belong to it. I refer to the billing of tolls, etc., and the collection of revenue of all kinds. With this in mind I have sketched the rough organization-outline shown in the accompanying illustration, in which I have shown the commercial department reporting to the vice-president as at present, but have defined the principal duties as (1) Public and other company relations, (2) Development, (3) Publicity. In other words, it would do all that is now assigned it except that the accounting and collecting end of the business would be transferred to the secretary and treasurer through the auditor (accountant). I have shown the secretary and treasurer responsible for (1) Revenue collection of all kinds, (2) Disbursements, (3) Cost studies.

Under this scheme the auditor and his entire force would report direct to the secretary and treasurer instead of to the president. This plan would eliminate much lost motion and duplication, hence be less expensive and promote efficiency. The present plan is confusing, as the lines between commercial and accounting are not clearly drawn; hence we find cashiers being employed by the commercial department and proving unsatisfactory to the auditing department, etc.

As a result of this confusion, the commercial department often neglects its most important duties, such as public relations and development. If greater attention could be paid to such matters much adverse legislation could be avoided, and rates and other means of producing revenue would also receive better attention. The work of the plant, traffic and auditing departments is well defined and understood, the major portion of it being routine, but with the commercial department only the smallest and least important duties are routine work. Every case presents new char-



ORGANIZATION CHART.

acteristics, new features, and requires careful individual attention along constantly changing lines. Believing that many of the more important commercial duties have been neglected in the past, this new plan is proposed as a means of eliminating many excuses on the part of managers, etc. The writer believes that cost studies, when necessary, should be in the hands of disinterested experts and can be handled to better advantage and with better results by being made a part of the duties of the accounting department.

The Municipal Electricians' Convention.

Intending exhibitors at the annual convention of the International Association of Municipal Electricians, which is to be held at Peoria, Ill., August 26 to 30, will be interested to know that there will be no charge for space. The exhibits will be located in a room adjoining the convention hall at the Jefferson Hotel. Mr. W. E. Wolgamott, city electrician, Peoria, Ill., will be glad to hear from anyone expecting to make an exhibit, and will give all the information at his command.

Members intending to attend the convention should also notify Mr. Wolgamott, so that he may be enabled to make proper arrangements.

The meeting promises to be of unusual interest to the members. Several valuable papers will be read and discussed, and a programme attractive in every respect will be prepared.

The Use of the Telephone in Railroad Service*.

BY G. K. HEYER, NEW YORK.

For the past four years a great deal of attention has been given by the progressive railroads to the improved method of handling train movements known as telephone train dispatching. There are, at the present time, approximately 285,000 miles of railroads in the United States and Canada, and the 55,000 miles of road which has been equipped for this new method of handling traffic stands as a monument to the success of the undertaking.

It is thought that a brief outline of the history of train dispatching would be interesting before going further into the subject.

Previous to the time of the introduction of the telegraph, trains were run on what was called the "time interval" system. With this system the ruling train had the right of one hour against an opposing train of the same class. Under this method of operation a great deal of time was lost if trains were late, and it was through the foresight of superintendent Charles Minot, of the Erie Railroad, that the telegraph, in 1850, made possible the abolition of the old "time interval" and "flag" system of advancing trains and the adoption of the telegraph dispatching system, which it was thought, for many years, possessed sufficient advantages to allow other branches of railroads to be developed to the greatest possible efficiency.

In recognition of the marked advance made by the use of the telegraph in 1850, the Association of Railway Telegraph Superintendents and the Old Time Telegraphers and Historical Association, are having erected at Turners, N. Y., a monument to the memory of Charles Minot, who, gave the first telegraphic train order from that point. [The monument was unveiled on May 2, as reported in the May 16 issue.—Ed.]

After the telegraph was first used by the Erie, there was begun, in 1851, a systematic attempt to telegraph orders from a central point to trainmen and conductors, and from that time up to the latter part of 1907 all train movements were directed by the telegraph.

While October, 1907, marks the first successful installation of telephone and selector equipment for train dispatching, there were previous to that time a number of roads which used the telephone equipment for handling train movements. As early as 1883 the New Orleans and Northeastern Railroad used the telephone for this purpose. The service was rendered over a grounded iron wire about 100 miles long, with the ordinary magneto telephone, as used at that time, and without the aid of the selector, which mechanism has made possible selective calling on long and heavily loaded railway telephone lines.

The telephone equipment used on all of these installations was far inferior to that in service at the present time, and the great improvements which have been made in the last two or three years in the telephone and selective apparatus, together with the new apparatus designed to meet the special requirements of the service, indicate that there are few, if any, requirements for communication to meet the conditions of railway service which cannot be met by the use of the telephone.

The New York Central was the first to install and actually operate trains by means of the telephone and selector equipment. Its first installation was completed in October, 1907, on a section of the main line between Albany and Fonda, with sixteen way-stations. The installation on the New York Central was closely followed by a number of installations on the Chicago, Burlington & Quincy, where in December, 1907, the main line between Aurora and Mendota, Illinois—a distance of forty-six miles, with eleven stations—was equipped. After this, a section from Aurora to Galesburg, Ill.—a distance of 125 miles, with sixteen stations—and another between Aurora and Clyde (the end of the Chicago Terminal), a distance of twenty-eight miles. These circuits all covered double track where reverse movements were made.

Within a short time after the completion of these circuits, and convinced from the results obtained that single track operations presented no problem which could not be solved by the use of the telephone, the Burlington equipped a single track section between Aurora and Savannah, Ill.,—a distance of 106 miles, with twenty-three way-stations.

These installations on the New York Central and Chicago, Burlington & Quincy produced the proof for which many had been waiting, and these roads can justly be called the pioneers in telephone train dispatching. The proof was so conclusive and the results obtained so satisfying that the subject became at once one of world-wide interest. This interest, however, until very recently, did not take the form of installations on railroad systems, except on railroad systems of the United States and Canada, and there are in these countries about twenty railroads which have over 1,000 miles of road equipped with telephones and selectors, the aggregate mileage for these twenty roads being approximately 40,000.

In spite of the success attending the early installations on the New York Central and Chicago, Burlington & Quincy Railroads, there were many things to be overcome before the adoption of the telephone and selector system could be made general. It is a well-known fact that a great many of the officials of railroads in this country have come up through the operating departments, and as these men had expressed themselves by means of the Morse key, they had come to consider the telegraph as much a part of the regular operation of the system as to believe it synonomous with quick, safe and efficient operation.

They were disposed to let well enough alone and could not feel themselves free to advocate the

* Proceedings of Railway Club of Pittsburgh.

Digitized by Google

use of a system which, to them, was comparatively new and untried. The attitude of the operators themselves also had a somewhat deterring effect on the adoption of the new system. There was a feeling among the dispatchers and operators that the passing of the telegraph would seriously affect their positions. Thus far, however, this has not been borne out, and the railroads have shown every disposition to retain the operators in their old positions. On serious thought this could only be expected, as the welfare of the railroad makes necessary the employment of men who know the railroad business, and in a few cases, if any, have operators lost their positions due to the adoption of the telephone, except as a result of some act of their own.

There were many who believed that the telephone would be satisfactory on double and multi-track operation, but there was much skepticism with regard to its use on single track roads. When carefully considered, however, it is believed that any means which would allow the dispatcher to more clearly express himself and thus relieve the traffic problem on double-track roads, would lend themselves with added benefits to the solving of more complex operations on single-track systems. This has been borne out by subsequent events and the single-track divisions are the ones in which the advantages of the telephone system are most apparent.

The early prejudices of the dispatchers and operators have been entirely overcome, particularly on divisions where the telephone system has been installed and not one out of the great number of dispatchers with whom I have talked would care to go back to the telegraph method of handling train movements. There are many dispatchers who, through the continual operation of the telegraph key, have developed operator's paralysis in a greater or lesser degree, and these men cannot speak too highly in praise of this system which, as some of them have expressed it, have given them a new lease on life.

(To be continued.)

An Interesting Bridge.

Before the days of the ocean cable the Western Union Telegraph Company had started to build a telegraph line from America to Asia, by way of the Behring Strait. Construction on the line was in progress, on both continents, says the *Railway and Engineering Review*, when the successful laying and working of the Atlantic cable caused the project to be abandoned. The line had been built well into British Columbia and in time the wires were pulled down by the Indians and appropriated for various uses. One use made of some of it was to build a suspension bridge across the canyon of the Bulkley river, but the structure wavered and teetered, and the Indians had misgivings as to the reliability of such material—they could put better confidence in timber, a material of construction with which they were more familiar. Accordingly, the present structure was erected, with logs and poles firmly lashed together.

The method of testing the strength of the structure was peculiar, or, at all events, something different from recognized practice with civilized engineers. According to Indian accounts, after the bridge was completed twenty squaws were selected as the "live" load and required to go to the center of the span, in a bunch, and execute a pot-latch dance. The bridge, having successfully withstood such a performance, the intrepid bucks confidently reasoned that a proper factor of safety for the passage of a man and a pack horse was assured.

We have taken pains to verify, officially, the source from which the Indians obtained the wire used in the original suspension bridge, says the *Review*, and here submit a statement from Mr. A. R. Brewer, treasurer of the Western Union Telegraph Company, New York:

"Our general manager has handed me yours of March 6 relating to the wires in a suspension bridge over the Bulkley river, in British Columbia, built by the Siwash Indians a number of years ago. The information you quote is correct. Even the river you mention was named after Colonel Charles S. Bulkley, engineer in charge of the Russian-American telegraph lines, and if you should chance to see a map of North America made, say, in the early seventies, you will find that there were in British Columbia and in Alaska forts (or depots) named after the Western Union directors which marked the route of the line. I distinctly remember seeing on such maps Fort Mumford and Fort Stager, which were named after Western Union directors of that day.

"The Western Union not only built or surveyed a line from New Westminster, B. C., to Alaska, but it built extensively in Asia and bought in Europe a cable to be laid at Behring Sea. The American end of the line was in charge of Colonel Charles S. Bulkley, and George Kennan, the Russian traveler, was connected with the Asiatic work and made his first literary success in the account which he wrote of his experiences entitled 'Tent Life in Siberia.'

"The first cable laid across the Atlantic Ocean, in 1865, failed after one or two messages, and its failure encouraged the Western Union Company to go on with the Siberian project. This failure was regarded as a demonstration of the impracticability of an Atlantic cable, but the remarkable persistency of Cyrus W. Field triumphed. He raised in England money to lay the second cable. The 'Great Eastern' was employed to lay it, and not only laid it successfully, but went back and repaired the 1865 cable. Soon after that happened the Western Union abandoned the Siberian project and all the money invested in it was lost."

EDISON BSCO PRIMARY BATTERY

The Standard Closed Circuit Cell

As a chain is no stronger than its weakest link, a telephone train despatching system is no more reliable than its most inefficient station.

Railroad accidents are not respecters of locality. They are as liable to occur in remote districts as on the more accessible parts of the road. It behooves the Telegraph Department, therefore, to fit each station for heavy, continuous service.

A transmitter cannot be expected to render its best service if the source of current which actuates it is not capable of maintaining uniform voltage so necessary for distinct transmission, under constant service.

All open circuit types of primary battery (dry cells coming under this classification), quickly polarize when discharged continuously at even a moderate rate, with a consequent drop in voltage. This weakening of the magnetic field in the transmitter naturally impairs the transmission.

It is self-evident that, unless a transmitter is supplied with a dependable source of current, the telephone system is liable to fail at the weak link, just at the time when highest efficiency is required.

If you stop to consider that the most highly developed type of closed circuit primary battery, the Edison BSCO is also the most economical in service, it is apparent that no good reason exists for taking a chance with a battery not fitted for the requirements, and thus running the risk of failure, under trying circumstances, of a carefully designed and constructed system.

The Edison BSCO cell is the latest Primary Battery development of the Edison Laboratories. It is the ideal battery for telephone talking circuits, on account of its long life, uniform voltage and low internal resistance.

The cheapest form of Primary Battery energy

Weaver Portable Test Set

For Railway Block Signal Systems

A VALUABLE asset to all signal engineers and superintendents of signals. The range of tests that can be made with this one instrument covers practically all the tests required to keep a signal system up to its highest efficiency. The set can be used to test the pick-up and drop-away in amperes, mil-amperes, volts and mil-volts of devices ranging from 4 to 3000 ohms resistance. and where voltage is concerned, vary from that employed in track circuits to 150 volts, the operating and hold clear current of low voltage, also high voltage interlocked signals can be measured up to 150 volts. The weight of the set is less than 10 pounds, making it very convenient and easy to carry. A special booklet describing this set more fully will be sent upon application.

Historical Sketch of Association of Railway Telegraph Superintendents.

A brief history of the Association of Railway Telegraph Superintendents will be of interest at this time.

The association was organized at Chicago, Ill., November 20, 1882. At this meeting officers were elected as follows: W. K. Morley, president; William Kline, vice-president, and C. S. Jones, secretary and treasurer.

At the second meeting also held in Chicago, June 13 and 14, 1883, there were thirty railroads represented. Mr. Morley was re-elected president; Charles Selden, vice-president, and P. W. Drew, secretary and treasurer. Mr. Drew has filled this position with credit to himself and the association ever since that time, being re-elected at each recurring meeting of the association.

At the third meeting, held September 17, 1884, in Philadelphia, Charles Selden was elevated to the presidency, and E. C. Bradley was elected vice-president.

The fourth meeting at Cleveland, Ohio, June 17 and 18, 1885, chose C. W. Hammond to succeed Mr. Selden, and elected as vice-president, George L. Lang.

The dates of the fifth meeting, which was held in St. Paul, Minn., were June 16, 17 and 18, 1886. At this meeting thirty-four railroads were represented, and the social feature of these conventions came into prominence, the guests being entertained by an excursion to Duluth and the Apostle Islands by rail and boat. A. R. Swift was elected president, and George L. Lang was re-elected vice-president.

The sixth convention was held at Boston, July 13 and 14, 1887. It was at this meeting that the practice of showing exhibits of telegraphic and other electrical devices was first introduced. George L. Lang was here elected to the presidency, and G. C. Kinsman was elected vice-president.

New York was the scene of the seventh meeting which met July 11, 1888. Edison's phonoplex system was shown in operation at this time and Mr. Kinsman was made president, C. A. Darlton succeeding him as vice-president.

Washington, D. C., entertained the eighth annual convention, which met October 16 and 17, 1889. Benjamin Harrison, who was then president, received the members of the convention in the White House. C. A. Darlton being elected to the presidency, George T. Williams was elected vice-president to succeed him.

The ninth annual gathering assembled at Niagara Falls, June 18 and 19, 1890. This convention was notable for the large number of papers read and the exhibition of the long distance telephone by which conversation was held with parties in Albany and New York. George T. Williams was elected to the presidency and George M. Dugan was elected vice-president.

At the tenth annual convention held at Cincinnati, Ohio, June 17 and 18, 1891, the number of railroads represented had increased to thirty-seven. This meeting elected C. S. Jones as president and L. H. Korty vice-president.

The eleventh in the series of conventions assembled at Denver, June 15 and 16, 1892. This meeting was largely attended, and was made notable by a paper by Thomas A. Edison. L. H. Korty being advanced to the presidency, U. J. Fry was elected to succeed him as vice-president.

The twelfth on the list convened at Milwaukee, June 20 and 21, 1893. The World's Fair at Chicago being then in progress, most of the members included a visit to this great exposition in their convention trip. U. J. Fry was elected president and O. C. Greene vice-president.

On June 13 and 14, 1894, the thirteenth annual convention met at Detroit. Following the usual custom, at this convention O. C. Greene was made president, and E. R. Adams was elected vice-president.

At the fourteenth annual convention held in Montreal, June 12, 1895, M. B. Leonard was elected president, and J. W. Fortune vice-president.

Old Point Comfort, Va., was the scene of the fifteenth convention which met June 17 and 18, 1896. Among other papers presented at this meeting was one by W. W. Ryder upon "The Telephone in Railway Practice." G. M. Dugan was elected president and J. W. Lattig, vice-president.

For the second time Niagara Falls was chosen as the place of gathering, the sixteenth annual convention meeting there June 16, 1897. J. W. Lattig being made president, W. W. Ryder was elected vice-president.

The most notable feature of the seventeenth annual convention which met June 15, 1898, at Omaha, Neb., was the report of a special committee upon low resistance relay experiments. W. W. Ryder was elected president and L. B. Foley, vice-president.

For a meeting place for the eighteenth annual convention the superintendents turned toward the South, gathering at Wilmington, N. C., May 17 and 18, 1899. L. B. Foley being elected to the presidency, W. F. Williams succeeded him as vice-president.

Detroit was then for the second time chosen as the convention city, the nineteenth annual convention meeting there June 20, 21 and 22, 1900. W. F. Williams was naturally elected to the presidency, and C. F. Annett was elected vice-president.

Buffalo was the scene of the twentieth annual convention which met in that city, June 19, 20 and 21, 1901. C. F. Annett being made president, F. P. Valentine was elected vice-president. This being the year of the Pan-American Exposition, an unusually large number were in attendance at this meeting.

For the third time Chicago became the scene of the convention, the twenty-first annual meeting being held there June 18, 19 and 20, 1902. Among the important subjects which came up for discussion at this convention were the questions of typewritten train orders and the use of the telephone in connection with railroad operation. J. H. Jacoby was elected president and W. J. Holton, vice-president.

The far South claimed the twenty-second annual

Digitized by Google

convention, which met in New Orleans, May 13, 14 and 15, 1903. The use of the telephone in connection with railway work again took a large part in the discussion. Mr. F. F. Fowle, of the engineering department of the American Telephone and Telegraph Company, presenting a lengthly illustrated paper upon "The Transposition of Telephone Lines to Prevent Cross Talk and Induction." At this time C. S. Rhoads was honored with the presidency and C. P. Adams became vice-president.

Indianapolis was the scene of the twenty-third convention in the series, which met in that city June 15 and 16, 1904. After the adjournment a side trip was made to the St. Louis Exposition. Henry C. Hope was elected president at this time and E. E. Torrey, vice-president.

The twenty-fourth annual convention met at Chattanooga, Tenn., May 17 and 18, 1905. The increasing use of high-tension transmission made very timely the paper of W. J. Camp upon "High Tension Wires on Railway Right of Way," which he presented at this meeting. E. E. Torrey was advanced to the presidency, and E. A. Chenery was elected vice-president.

The superintendents again turned their faces toward Denver, the twenty-fifth annual convention meeting there June 20 and 21, 1906. The question of high-tension wires again came up and occupied a large place in the discussion. E. A. Chenery was elected to the presidency and E. P. Griffith was elected vice-president.

Atlantic City, N. J., the popular waterside resort, entertained the twenty-sixth annual convention, which met June 19, 20 and 21, 1907. An unusually large number of interesting papers were read at this meeting, and some most interesting discussions developed. E. P. Griffith was advanced to the presidency and W. J. Camp succeeded him as vice-president.

The twenty-seventh annual convention met in Montreal June 24, 25 and 26, 1908. W. J. Camp was elected president and G. W. Dailey vice-president. Upon Mr. Dailey's promotion from the position of telegraph superintendent of the Chicago and Northwestern to the superintendency of the Wisconsin division of that road, J. B. Fisher was elected by the executive committee as vice-president.

The 1909 convention was held at Detroit June 23, 24 and 25, with about seventy-five active members present. J. L. Davis of Chicago was selected to head the organization for the ensuing year and Los Angeles was selected as the place of meeting for the 1910 convention.

The twenty-ninth annual convention met at Los Angeles, Cal., June 20-24, 1910, and notwithstanding the great distance for most of the members to travel, there was a large and enthusiastic attendance. Isaac T. Dyer of Los Angeles, Cal., was elected president. At this meeting the movement to erect a monument at Turner, N. Y., to commemorate the sending of the first telegraph train order (in 1851) was officially sanctioned and a committee appointed to carry the proposition into effect.

Boston was the meeting place of the thirtieth convention, which was held June 26-28, 1911. The meeting was largely attended, and many valuable and practical papers were presented and discussed. In the absence of president I. T. Dyer, on account of illness, vice-president J. B. Sheldon presided at the meetings. G. A. Cellar was elected president and Wm. Bennett vice-president.

It was decided to hold the 1912 convention in New York June 24, but on account of the fact that the national political conventions were to be held about the same time the executive committee of the association changed the date of the meeting to June 4.

Pioneer Telephone Train Dispatching.

The following article taken from the *Mountain States Monitor* will be of interest at this time in connection with the convention of Railway Telegraph Superintendents.

Mr. C. F. Annett, an old-timer and formerly assistant superintendent of telegraph of the Illinois Central Railroad, Chicago, is the author of the article.

He says: The Utah & Nevada Railway Company was one of the first railroads to adopt the telephone exclusively for dispatching and operating its trains. This was in 1884. The railroad extended forty miles from Salt Lake City to Stockton, Utah. At that time Garfield Beach, on this railroad, was the only bathing resort on the Great Salt Lake, and the traffic between the city and the resort was very heavy in the bathing season.

I was general manager of the Rocky Mountain Bell Telephone Company at the time the telephone line was put in. We built it along the railroad right of way. E. G. Holding was foreman of construction and John Bellamy was a lineman on the work. Both of them are still living at Salt Lake City. They were very competent construction men and are the only members of the construction force that I recall now.

Captain Dorris was manager of Garfield Beach and also acted as toll agent for the telephone company there.

Telephones were located at two passing stations between Salt Lake City and the beach, where conductors received their orders. Many trains were handled during the afternoons and evenings in the resort season and not a single accident occurred during the several years that the telephone train dispatching was in use.

The second railroad in the West to adopt telephone train dispatching was also a Utah road.

Hawthorne on Post Cards.—A series of views of the Hawthorne works of the Western Electric Company has recently been arranged for post card use and is intended to give the company's friends a better idea of what the "Electrical Capital of America" really is and what is being done there, industrially and socially. The series consists of twelve views showing a general view of the works and some of the principal departments. The post cards are actual photographs and are remarkable for their clearness and fine detail.

EVERYTHING

Western Electric

MEANS

Everything to Railroads

TELEPHONE EQUIPMENT of established and reliable quality. Our customers benefit by our more than 30 years' experience as the sole manufacturer of "Bell" telephone equipment. Western Electric high efficiency transmission circuit is the only answer for railroad telephone lines.

SELECTOR EQUIPMENT that is simple and dependable—entire satisfaction wherever installed.

OTHER APPARATUS—iucluding testing and patching panels, repeating and retardation coils, special switching devices—in fact, a Western Electric answer to every problem.

LINE MATERIAL, TOOLS AND SUPPLIES furnished by the Western Electric Company—the best of their kind.

COMPLETE STOCKS at our various distributing houses at our customers' disposal. May they never need an emergency shipment; when they do—they will find us ready.

PRICES as low as is consistent with high quality. The price is forgotten but the quality remains as a tribute to our mutual good judgment.

ENGINEERING SERVICES at the railroads' disposal.

INCREASE Your Efficiency and You Will Increase Your Employer's Appreciation & Becoming a Stockholder in the Company Employing You Would Be a Step in the Right Direction.

EVERY INDIVIDUAL should be a stockholder in the Company that furnishes him with Employment. How to do this is easily explained in my partial payment plan which enables you to buy one share or as many as your salary will permit. The partial payment plan helps you to save money, and in time offers other opportunities that YOU cannot hope to obtain in any other way.

THE DIFFERENCE in buying stock on the PARTIAL PAYMENT PLAN and buying a suit of clothes on the instalment plan is, that you eventually own the stock and become a voter in the company employing you. If any misfortune overtakes you, realization on your stock is practically as easy as drawing from a savings bank and like Insurance you are protected in the interim.

THE INITIAL charges would be seven dollars to thirty dollars per share depending upon the stock and p ice, not selling above one hundred and fifty dollars a share. The minimum commission charge would be one dollar. Six per cent interest would be charged on the difference between your margin and the cost of the stock until paid for in full when you could have the same transferred to your name.

Programme of Convention of Railway Telegraph Superintendents.

The entertainment committee has decided to abandon the proposed clambake at Traver's Island on Friday, June 7, and have a banquet in the city instead.

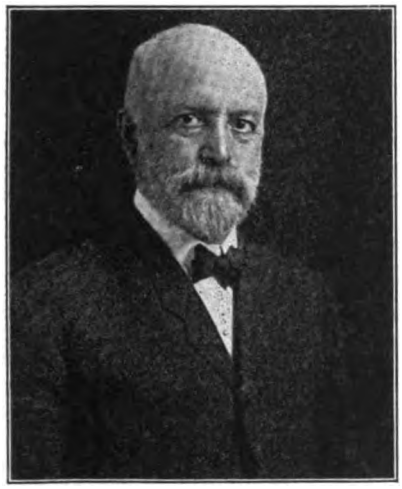
Following is the complete programme of the convention.

Monday, June 3, 8 p. m., informal reception in the East Room of the Waldorf-Astoria.

Tuesday, June 4, 10 a. m., business session. Two p. m. paper on "Construction Material and

G. A. CELLAR, PRESIDENT.

Methods," by Mr. R. E. Chetwood, engineer of construction, Western Union Telegraph Company, New York; 3 p. m., paper on "Some Facts Regarding the Handling and Recording of Supplies," by



P. W. DREW, SECRETARY.

Mr. W. G. Higgins, superintendent of supplies, Western Union Telegraph Company, New York; 4 p. m., paper on "Some Notes on Polarized Sounders in Telegraphy," by Mr. Wm. Maver, Jr., New York. The ladies will be taken on a sightseeing tour in automobiles in the afternoon and at night there will be a theatre party given by the New York Telephone Company. The play will be the "Two Little Brides," at the Lyric Theatre, 231 West 42nd street.

Wednesday, June 5, 10 a. m., paper on "The Use of the Main Line Relay in Telephone Selector Operation," by Mr. W. W. Ryder, general superintendent of telegraph, New York Central Lines West, Chicago, Ill.; 11 a. m., paper on "Telegraph Traffic," by Mr. W. N. Fashbaugh, traffic engineer, Western Union Telegraph Company, New York; 12 o'clock, noon, paper on "St. Louis Terminal Telegraph and Telephone Facilities," by Mr. F. E. Bentley, superintendent of telegraph, Terminal Railroad Association, St. Louis, Mo. In the morning there will be a shopping tour for the ladies. At 2 p. m., the men will

WALDORF-ASTORIA—HEADQUARTERS OF ASSOCIATION.

take stages at the Waldorf and be conveyed to the Spring Exchange of the New York Telephone Company which they will inspect, and at 3.15 p. m. they will be conveyed by the same means to the Western Union Building at 195 Broadway. They will inspect the telegraph headquarters for an hour and at 5 o'clock the entire party will reunite at Pier 1 North River and board a steamboat for Coney Island where the visitors will be entertained in the usual Coney Island manner. The party will then be free to return to the city by rail at their pleasure.

Thursday, June 6, 10 a. m., paper on "What the Telephone Has Done for the Santa Fe Railroad," by Mr. L. M. Jones, superintendent of telegraph, Atchison, Topeka and Santa Fe Railway, Topeka, Kan.; 11 a. m., paper on "The Maintenance of Telegraph Lines," by Mr. G. M. Yorke, engineer, Western Union Telegraph Company,

Digitized by Google

New York; 12 o'clock noon, paper on "The Use of Portable Telephones in Railroad Service," by Mr. J. F. Caskey, superintendent of telegraph, Lehigh Valley Railroad, South Bethlehem, Pa. Adjournment will then be taken for lunch, and at 2 p. m., a paper will be read on "Telegraph Line Maintenance," by Mr. W. S. Melton, superintendent of telegraph, Queen & Crescent Route, Danville, Ky. At 3 p. m. the election of officers will take place. The ladies will be taken on a trip around Manhattan Island by boat and at 8 p. m. the entire party will attend a performance at the Winter Garden, Broadway and Fiftieth Street.

On Friday the entire party will board a special train on the Erie Railroad at 9:30 a. m. and be conveyed to West Orange, N. J., where they will inspect the Edison works. The visitors will be entertained at luncheon at the Edison plant at West Orange as the guests of Mr. Edison, after which they will return to New York over the same route. In the evening at 7:00 o'clock there will be a banquet at Martin's, Forty-second Street and Broadway.

The Railroad.

Mr. L. G. Jackson, trainmaster in charge of transportation and telephone service, Philippine Railway Company, Iloilo, P. I., arrived in New York, May 21 from the Philippines by way of Europe on the steamer "Kaiser Wilhelm II." Mr. Jackson expects to attend the Convention of Railway Telegraph Superintendents in New York on June 4.

Mr. Joseph P. Church whose appointment as superintendent of telegraph of the Wabash Railroad, with headquarters at Decatur, Ill., was announced in the May 16 issue, was born in Toledo, Ohio, December 13, 1856, and took up telegraph work July 5, 1870, as messenger at Toledo. He subsequently became delivery clerk and then an operator, and between 1877 and 1893 filled the position of assistant chief operator and electrician. January 1, 1893, he was appointed manager of the Wabash telegraph office at Decatur, and on October 1, 1898, became chief clerk to the superintendent of telegraph of that road.

Except temporary service with the Great Northern Railway at Minot, N. D., from August, 1905, to January, 1906, as Western Union manager and division operator and a few months during 1905 as foreman on the Wabash railroad, Mr. Church has been in the continuous service of the Western Union Company since 1870. He received his present appointment as superintendent on May 1.

O. R. T. Convention.—The Order of Railway Telegraphers, Dispatchers, Agents and Signalmen, held its annual convention in Reading, Pa., May 13, 14 and 15. Mr. J. R. T. Auston was re-elected president; Adam Reed, grand secretary and treasurer and J. F. Tatlow, first vice-president. The next convention will be held in Harrisburg, Pa.

The Turner Monument Fund.—Since the dedication of the telegraph monument at Harriman, N. Y., on May 2, an additional subscription toward the fund has been received. The fund now stands as follows: Previously acknowledged, $2,331.09. H. F. Merriman, New York, $1.00; refund on insurance on bronze tablet, $7.50. Total, $2,339.59.

Baltimore & Ohio to Install More Telephones.

The Baltimore and Ohio Railroad, of which Mr. Charles Selden is superintendent of telegraph, has recently placed another order with the Western Electric Company for selector equipment to be used in extending its facilities for dispatching trains by telephone. The division to be equipped extends from Cincinnati, Ohio, to Montgomery, Ind., and, branching off at Seymour, Ind., to go to Louisville, Ky., and Jeffersonville, Ind. There will be three parallel circuits, a train wire, a message wire and a block wire. A feature of the message wire is that it is arranged for "inter-calling," or, in other words, way-stations can call one another. The apparatus to be used is the Western Electric No. 102-B type selector set, containing the No. 50 type selector. There will be one hundred selector stations so equipped, covering a stretch of approximately 250 miles. In all there will be over 800 miles of circuit for train, message and block service.

The Lehigh Valley Installs Additional Telephone Dispatching Apparatus.—With the installation of the additional apparatus recently ordered from the Western Electric Company, the Lehigh Valley Railroad will have equipped all except about 150 miles of its entire system, including main lines and branches, with telephones for train dispatching. A further extension is now being planned. The division to be equipped is the Elmira and Camden Branch, extending over approximately 140 miles of road, wholly within New York State. The dispatcher is to be located in the middle of the line at Cortland, N. Y., and will handle both dispatching circuits, one of which goes to Elmira and the other to Camden. So that two calls may be placed simultaneously on either end of the line, individual calling apparatus is used for each circuit. Thirty-five way stations are to be equipped with Western Electric standard selectors and auxiliary apparatus. Signaling and talking current will be furnished from the dispatcher's office by storage batteries charged by a 1 k.w. motor-generator set. A feature of the Lehigh Valley's circuits is an automatic switching or inter-connecting arrangement which enables the dispatcher on any one division to communicate with the dispatcher on another. This furnishes a means of obtaining information about trains on other divisions before they arrive at divisional terminals. Mr. J. F. Caskey, South Bethlehem, Pa., is superintendent of telegraph.

Gill Selector Service

¶ Railway Telegraph Superintendents know that it means continuous, dependable, twenty-four hours-a-day efficiency, year after year.

¶ Lower maintenance cost than can be shown by other types.

¶ Wherever selectors have been subjected to comparative service tests, the Gill Selector has been chosen as standard over all others.

¶ But ONE contact between the dispatcher and the bell.

United States Electric Company

NEW YORK CHICAGO

Concrete Poles.

Mr. P. H. Burns, who has charge of the electrical department of the Bahamas, with headquarters at Nassau, in a recent letter to this publication states that he has constructed some 400 reinforced concrete poles, which are now in service, and has yet 200 more to make to take the place of wooden poles now in use. "These poles," he says, "are great, and have so far laughed at our hurricanes."

Mr. Burns contemplates the construction of a wireless telegraph station for the Government. Bahamas is up-to-date on all electrical matters. The island is connected with Florida by a submarine cable, the telephone and electric-light systems are modern and the contemplated wireless telegraph plant will make the island complete in its up-to-date methods of communication and lighting.

Mr. Michael Fitzgerald, of East Brewster, Cape Cod, Mass., a well-known old-time cable operator, who is now engaged in literary work, in renewing his subscription to our paper writes: "TELEGRAPH AND TELEPHONE AGE is surely a boon to the fraternity. I study it with great interest and I often wonder if members of the craft are appreciative of its invaluable aid to all who aspire to attain something more than a dot-and-dash knowledge of the business. I hear very little from others of what is going on in the service. Indeed, the AGE is my sole informant."

"C. Q. A." RELAY
(Champion Quick Adjustment)

THIS IS THE LATEST

development of our high grade No. 1 instrument. It is the result of long experience, and an intimate knowledge of what a perfect Relay should be, combined with mechanical skill and the best materials that can be obtained for the purpose.

We have designated it the C. Q. A. or Champion Quick Adjustment Relay because with our new magnet adjustment the magnets may be instantly moved to any desired distance from the armature. The armature tension spring adjustment is also simplified and improved. The C. Q. A. Relay is very compact the dimensions of surbase being only seven and one-half inches long by three and one-half inches wide. The C. Q. A. Relay is mounted on slate instead of wood. It is furnished with the latest style of W. U. clamp connections to which the magnet and local wires are soldered, thus making such a thing as a loose connection impossible. The magnets are supported and protected by a spectacle frame. An automatic stop prevents contact between the magnet cores and the armature.

The C. Q. A. relay will be furnished regularly with hardened silver contact points as adopted by the Western Union and Postal Telegraph Companies.

Net Price wound to 150 ohms . . $3.00

Prices on special windings and on quantities will be quoted on application.

We are *Pioneers* in the making of DRY CELL BATTERIES and confidently assert that our NEW JOVE BATTERY is the BEST DRY CELL ever produced.

It has the *Greatest Voltage, Amperage* and *recuperating qualities.*

THE JOVE DRY CELL

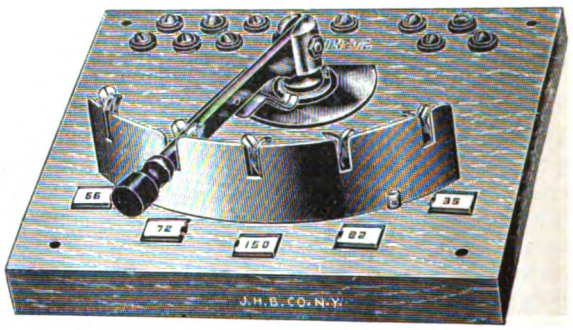
It is *unequalled* for heavy work, such as *Selector Systems, Gas* and *Gasoline Engine ignition* whether stationary or in *Autos, Motor Boats, etc.*

A *trial order* will convince the most skeptical.

We *guarantee* every cell and will refund if not satisfied. Get our prices.

THE RAMSAY TABLE INSTRUMENT SWITCH

(Patented)



Made in two sizes for 5 or 10 lines

The neatest, quickest, best and slickest switch ever devised for putting a particular set of instruments on any line connected to it. Simply move the pivoted arm to proper line slot and press down.

Obituary.

Col. A. C. Waterhouse, aged 80 years, a former telegrapher, died in Chicago, May 13.

R. M. Ford, aged 58 years, manager of the Western Union Telegraph office at Jeffersonville, Ind., died at that place May 14.

A. J. Clarke, aged 44 years, for many years an operator for the Western Union Telegraph Company and a clerk in the city engineer's office, Baltimore, Md., died in that city May 10.

R. H. Orton, son of the late William Orton, former president of the Western Union Telegraph Company, died at Irvington-on-the-Hudson, May 22. Mr. Orton was in the insurance business.

Judge Mabec, chief commissioner of the Canadian Board of Railway Commissioners, who was mentioned in our issue for May 16 in connection with the investigation of press rates in the Dominion as being ill, has since died.

Telephone Pioneers.

The membership of the Telephone Pioneers of America is rapidly increasing, largely through the activity of the recording secretaries in different sections of the country. It now numbers about 800, including thirty-five ladies. Many of new members are from the Pacific Coast.

Mr. W. B. T. Belt, general superintendent of plant, Nebraska Telephone Company, Omaha, Neb., has been appointed recording secretary for the jurisdiction of the Nebraska group of companies.

Secretary Henry W. Pope, of New York, has received a supply of membership pins and watch charms of solid gold and gold plate. They represent the association's well-known triangular emblem, the lettering, etc., being inlaid with enamel. They are for sale to the members.

Annual Meeting of the A. I. E. E.

The annual meeting of the American Institute of Electrical Engineers was held May 21 and officers were elected as follows: Ralph D. Mershon, president; William S. Murray, A. T. Beresford and S. D. Sprong, vice-presidents; Professor Comfort A. Adams, William B. Jackson, William McClellan and J. F. Stevens, managers; George A. Hamilton, treasurer, and F. L. Hutchinson, secretary.

A bronze bust of Joseph Henry, by Mr. Herbert Adams, was presented to the Associazione Elettrotecnica Italiana as a token of appreciation of its gift to the Institute, some years ago, of a bronze bust of Galileo Ferraris and in partial recognition of the courtesies to the president and members of the Institute at the international congress at Turin.

Prof. M. I. Pupin, of Columbia University, New York, made an address on "The Debt We Owe to Henry as a Scientist." Mr. John C. Barclay, formerly assistant general manager and electrical engineer of the Western Union Telegraph Company, New York, spoke on "Henry as the Inventor of the Telegraph."

Employes as Stockholders; The Benefits to Accrue.

BY J. FRANK HOWELL, NEW YORK.

Did you ever stop to think what it would mean to own one or more shares in the company employing you? A voting proxy—small—yes, but not without its effect.

It has always been my contention that every employe, especially telegraphers, regardless of the employing corporation, should strive to be a stockholder in it; that is, of course, if it is a creditable institution, and no one knows this better than the employes. To some this may not seem easy, but like opening a saving bank account, the start is the greatest obstacle. When this is once overcome the rest is comparatively easy to those having steady employment, providing they do not undertake to do too much.

Facts and figures prove that it is to the interest of every one having a little money to invest it in a well-managed property where it will reap the benefits of good association. Moreover the standing of the small property owner in a community is on a higher plane than that of the individual similarly employed, but with no property of any kind. It is the same with the employe-stockholder; his importance towers above the non-

J. FRANK HOWELL,
A Governor of the Consolidated Stock Exchange, New York.

stockholder until it is noticed at home and abroad. Besides this his financial standing is gradually yet continually strengthening.

Earnest, energetic people who desire to make money can never expect to make it, without some deprivation on their part. There is no secret to money-making; the principle is the same in every line of business. Successful saving is based on judgment and patience coupled with a sufficient force of character to control the same. After this the rest is limited only by one's own effort.

A promising sign of the times is the growing appreciation of employes of the advantages attaching to ownership of stock in the companies for which they are working. Such ownership establishes a mutuality of interest that operates to the benefit of both the employer and employe. It makes for stability and good feeling. It gives to the wage-earner a sense of proprietorship that makes him a little more careful of his time, which increases his efficiency and contributes to the strength of the corporate structure.

Digitized by Google

During the past twelve years there has been a steady increase in the number of small shareholders in our railroad and industrial corporations. A very considerable percentage of these small holders are workingmen who have fallen into the habit of putting their savings into the properties with which they are identified. In a sense it is a development of the profit-sharing plan in force in many manufacturing concerns in this country and the old world. It brings capital and labor into closer and friendlier relationship. It is an insurance against strikes and other forms of waste, loss and violence, always incident to methods of settling disputes under conditions now happily passing into merited disfavor.

More than that, it is practical patriotism. The greater the extent of associated ownership in the business of the country the stronger the guarantee against the assaults upon our institutions by the dangerous elements of society. Every man who becomes financially interested in the success of the business in which he is engaged is a vote for the permanency of the home.

Investment of savings in the stocks of well managed business enterprises will not altogether supersede the practice of depositing in savings banks or investing in building and loan associations, but it is along the same lines and should be encouraged. It is what has made the humbler classes of France the greatest money power in the richest nation (per capita) on earth. In the course of time the American small investor will bulk stronger and have greater influence than the so-called money power or money trust. Things are working that way rapidly and with inexorable certainty.

Decorating the Morse Statue.—The Morse statue in Central Park, New York, was decorated this year as usual by Mr. M. H. Kerner of 195 Broadway. The work was done under the auspices of the Morse Electric Club.

Sudden Deaths of Operators.

Harry C. Stough, aged 49 years, a telegrapher, committed suicide in Toledo, Ohio, May 22.

Samuel I. Herschberger, aged 59 years, an operator for the Western Union Telegraph Company at Albany, N. Y., committed suicide by shooting, on May 25. He had been in the employ of the company for forty years.

LETTERS FROM OUR AGENTS.

PHILADELPHIA POSTAL.

A message of sympathy from this office, in the form of a floral wreath, was sent to the home of M. A. Baker, wire chief, whose father died May 23.

Mr. D. McNicol, of the engineer's office, New York, was a recent visitor.

The strawberry season is now at its height and the early morning force has been increased accordingly.

M. Frankel went to Rose Tree May 25 to take care of newspaper file during the races.

NEW YORK WESTERN UNION.

Thomas J. Floyd, aged 60 years, an old-timer and a "shining light" in the telegraph profession some years ago, died in New York May 14.

An order has been posted in this office requiring office girls to "wear plain shirtwaists with moderate high adjustable collars and sleeves that extend below the elbows."

The Telegraphers' Mutual Benefit Association, 195 Broadway, New York, enables telegraph and telephone employes to provide for their families life insurance in reasonable amounts, at a cost so low as to be within the reach of all. It has already paid beneficiaries of deceased members $1,650,000, at an average annual cost per $1000 of about four cents a day, and has also accumulated $328,000 Reserve Fund securely invested, to provide against excessive cost in the future. Membership is easily acquired and cannot be invalidated during life for any cause except failure to pay the necessary mortuary calls.

SOME POINTS ON ELECTRICITY.

BY WILLIS H. JONES.

Concerning the Adjustment of Contact Points.

The question of how much play a lever should have between its contact points for best results, is frequently asked and discussed by attendants handling telegraph apparatus, yet opinions differ so widely that a little information concerning the factors which should govern the width of the air gap may help bring about a better understanding.

To begin with, there can be no fixed degree of play for any given instrument, except for circuits in which it is used for a specified purpose and where the current and other conditions are also a fixed or known value. In other words, the "play" varies as the conditions vary.

The general understanding is that the adjustment of a relay is to be made solely by means of the magnet control and the retractile spring. Of course this constitutes the fundamental principle of adjusting, but with a given current the degree of play allowed between contact points makes a marked difference in the distance to which the magnet must be withdrawn, or in the spring tension. For illustration: if we take a four-ohm relay and adjust it so that the air-gap between the magnet and the armature is equal to the thickness of a sheet of tissue paper and then give the lever an almost imperceptible play between the contact points, it is possible to operate it by the key with so feeble a current as two milliamperes. Yet, should the play be then widened in the slightest degree, it may not operate on less than ten or twenty milliamperes. By further widening the play to a maximum of 1/8 of an inch, or a little more, the volume of current necessary to operate it will increase to probably 150 milliamperes, or more, thus demonstrating the fact that with a given magnet and tension adjustment the degree of play governs the range of current values the instrument will respond to without other attention.

Again, the proper amount of play to give the lever of a relay depends upon the condition of the circuit and what is required of it. If the current flowing is weak, and rapid signals are to be made, obviously a minimum play should be given, but if intended for a signal lamp relay where it is expected to be non-operative on a given volume of current, but to close with an excess of current, the rear contact point if moved back slightly will alone make it non-operative to the normal current in the local circuit and responsive to the excess only.

There is one point that should be remembered particularly, and that is, when the lever falls to the back contact point the effect is the same as though the magnet had been withdrawn slightly, hence it requires more current to start the armature forward than is required to hold it there after being restored. The wider the gap the more current required.

Another point is that with a fixed volume of current flowing through the coils it requires a smaller excess of current to close the relay than it could be operated with by key had there been no original current, and also, under these conditions the lever points once closed will remain closed after the excess current has by means of a rheostat been decreased considerably below the volume that would otherwise be required to hold the armature. This phenomenon explains the tendency of relay points to "stick" during wet weather, which, owing to escapes, causes operation to be affected by the increase and decrease method instead of a clean removal of magnetizing energy when a key is opened. It would appear, therefore, that such an adjustment of contact points that prevents undue alterations in the width of the air gap between the magnet and the armature tends to prolong the life of the adjustment. Hence, for current in external Morse circuits the contact points of electromagnets should be maintained as close as is practical. Wet weather demands this adjustment, although dry weather is not so exacting and offers practically the only excuse for wide points.

For local circuits the same instrument demands wide contact points when used for one purpose and close points for another. Take, for example, a repeating sounder. When the points are used as

Digitized by Google

a shunt to supply a substitute current or shift a circuit it must be done as quickly as possible, hence the points should be very close, as in the case of some types of single line repeaters using them. This adjustment applies particularly to relays and transmitters used in connection with Toye repeaters and modifications thereof. On the other hand when a repeating sounder is used as a "bug catcher" on the common side of a quadruplex the contact-point gap should be wider, in order to increase the distance between the front and back contact points so that the armature cannot be attracted during the very brief period of no magnetism, hence the multiplex relay which controls it loses temporary control of its armature.

In the automatic printing telegraph system the contact points of one of the relays are given so wide a play that a small lever is enabled to make five or six contacts successively during the period occupied by the relay lever in reaching its front stop.

In the case of "buzzers" wide contact points admit of fewer strokes per second than do closer adjustments, for a given strength of current, all of which goes to show that contact-point adjustment, like everything else, is a subject for special study in individual cases, as it is governed by existing conditions and not by any set rule.

Tests of Cross Arms.—The Department of Agriculture has issued a pamphlet on "Strength Tests of Cross Arms," by T. R. C. Wilson, assistant engineer in forest products.

Personal.

Mr. S. D. Field, the electrical engineer of Stockbridge, Mass., was a recent New York visitor.

Mr. L. F. Philo has been appointed sales manager at Buffalo for the Western Electric Company.

Mr. Harry E. Dunham, former assistant editor of TELEGRAPH AND TELEPHONE AGE, will be married on June 26 to Miss Julia Louise Reynolds, at Baldwinsville, N. Y.

Miss Ruth Hough, daughter of Mr. I. D. Hough, of Omaha, Neb., a well-known telegrapher in the west, was married May 15 to Mr. J. O. Butler, of Olivet, Mich.

Mr. Edward Connett, commissioner of public utilities in New York, who recently was made vice-president of the National Utilities Company, Buffalo, N. Y., was at one time a telegraph operator.

Lieutenant G. R. Guild of Washington, D. C., will read a paper at the annual meeting of the American Institute of Electrical Engineers in Boston on June 24 on the subject of "Polarized Sounders."

Mr. Geo. M. Myers, an old-time telegrapher of Kansas City, Mo., has just returned home from a trip around the world. He was accompanied by his wife and daughter and reports enjoying every minute of the time he was absent.

Postal Telegraph-Cable Company.

EXECUTIVE OFFICES.

Mr. E. J. Nally, vice-president and general manager, New York, received the congratulations of his many friends on the fifteenth anniversary of his wedding June 10.

Mr. J. G. Blake, general superintendent, San Francisco, Cal., is in New York on company business, and will not return to the Pacific Coast until about June 20.

Mr. W. J. Camp, assistant manager Canadian Pacific Railway Company's Telegraph, Montreal, Que., and Mm. Marshall, superintendent, Canadian Pacific Railway Company's Telegraph, Toronto, Ont., were recent executive office visitors.

Mr. D. McNicol of the electrical engineer's office, has returned from a trip to Philadelphia, Buffalo and other points in New York State on company business.

Messrs. F. F. Norton, superintendent of traffic, and P. J. O'Donohue, division electrical engineer, New York, have gone to Chicago in connection with the Republican national convention.

Miss Thalia N. Brown, chief clerk to Mr. E. J. Nally, vice-president and general manager, New York, will sail for Europe on the steamer "Adriatic" of the White Star Line, June 27. Miss Brown will visit England and the principal continental countries and will be gone two months.

On Decoration Day the employes of the supply department placed a floral wreath upon the grave of the late W. D. Francis.

Digitized by Google

Mr. H. R. Cook, manager of the Postal Telegraph-Cable Company at Pittston, Pa., has resigned on account of ill health. Mr. Cook has been appointed district grand deputy for the Heralds of Liberty, a fraternal insurance company, for several counties in Pennsylvania.

The arrangements for handling the heavy traffic incident to the National conventions at Chicago and Baltimore are very complete, and were carried out under the direction of Mr. M. M. Davis, New York, electrical engineer and superintendent of telephones. Mr. H. C. Shaw will be in charge of the electrical equipment at Chicago and Mr. J. P. O'Donohue, of electrical engineer's office New York, will be in charge at Baltimore.

The library of the employes of the Postal and of the Commercial Cable companies, New York, has been moved into larger quarters on the tenth floor. There are now 1200 volumes in the library. Miss Elizabeth Allen is the librarian.

Postal Conference in Atlanta.

A conference of managers in the Southern division of the Postal Telegraph-Cable Company was held at Atlanta, Ga., May 23, 24 and 25, in the offices of general superintendent G. H. Usher. Mr. A. M. Beatty, manager, Atlanta, read a paper on "Pick-up-Telephone and Delivery Service," and one on "Business Getting," was read by Mr. A. P. Martin, manager, Nashville, Tenn. "Office Organization" was discussed by Mr. T. D. Jackson, manager, Birmingham, Ala.

On May 23 the party attended the theatre in a body and in the evening of May 24 a banquet was held at the Capital City Club, Mr. G. H. Usher, acting as "chef." Jesse Hargrave, division superintendent, Atlanta, responded to the "roast" "Electric Currents and Other Shocks;" superintendent G. W. Ribble, "The Visiting Managers, the Boosters' Club;" superintendent W. C. Daviet, "Postal Telegraph Club, Just a Few Splinters;" superintendent W. C. Lloyd, "Postal Spirits, Intoxicating but Non-Alcoholic," and superintendent C. H. Ashburn, "The Absent Managers, On the Job and Not Forgotten." The banquet concluded with a standing toast to president Clarence H. Mackay.

Among those present, in addition to those already mentioned, were the following managers: J. C. Dolive, Tampa, Fla.; H. R. Waterbury, Jacksonville, Fla.; W. T. Austin, Savannah, Ga.; C. M. Grier, Macon, Ga.; Fred L. Wood, Augusta, Ga.; C. H. Johnson, Memphis, Tenn.; L. W. Janes, Louisville, Ky.; J. S. Greever, Chattanooga, Tenn.; J. J. Barnett, Knoxville, Tenn.; N. E. Church, New Orleans, La.; W. B. Cole, Pensacola, Fla.; W. R. Hurst, Mobile, Ala.; F. A. Bivins, Montgomery, Ala.; R. C. Hackett, Vicksburg, Miss.; H. A. Lanier, Norfolk, Va.; W. O. Gaffney, Charlotte, N. C.; C. T. Snydor, Richmond, Va.; W. B. Stuart, Columbia, S. C.; W. E. Harrington, Atlanta, Ga.

The following members of the Postal Telegraph Club of Atlanta attended the banquet: C. H. Ashburn, Jr., J. E. Arnold, William Boles, J. Bartlett, T. L. Cameron, C. Cowan, D. C. DeLaney, J. D. Ewing, F. H. Floyd, R. D. Guinn, F. H. Howell, J. F. Heard, C. E. Harrison, W. H. Jackson, C. G. Knapp, J. H. McKerley, L. A. Minor, G. W. Oliver, H. W. Pearce, F. F. Pursley, E. E. Roberson, W. E. Sitton, J. A. Spurlock, R. L. Strong, H. P. Thornton and R. F. Williamson.

J. Nering, Manager Postal Telegraph-Cable Company, Chicago.

Mr. John Nering, whose appointment as manager of the Chicago office of the Postal Telegraph-Cable Company was announced in our May 16 issue, is a native of Chicago, having been born there on December 5, 1871. He entered the telegraph service as messenger for the Western Union Company in Chicago in June, 1884, and his entire business career has been spent in that city.

J. NERING,
Manager Postal Telegraph-Cable Company, Chicago.

While in the Western Union service he advanced from messenger through the positions of clerk and operator in branch offices and in September, 1889, entered the employment of the Postal Telegraph-Cable Company as operator in the sugar and coffee district branch office, of which he became chief operator in May, 1893, and on December 5, 1900, he was appointed manager. He was transferred to the main office August 25, 1904, as assistant manager in charge of branches, and on May 1 of this year was advanced to the managership.

May Destroy Messages.—The interstate commerce commission has granted telegraph and cable companies permission to destroy all original messages sent by the public after being preserved for one year.

Mr. H. A. Tuttle, president and general manager of the North American Telegraph Company, Minneapolis, Minn., writes: "If you had not renewed my subscription to TELEGRAPH AND TELEPHONE AGE there would have been trouble. In it I always find more than the money's worth."

Western Union Telegraph Company.

EXECUTIVE OFFICES.

Mr. Theo. N. Vail, president of the American Telephone and Telegraph Company and of the Western Union Telegraph Company arrived from Europe June 12 on the steamer "Olympic."

Mr. L. H. Beck, division plant superintendent, Atlanta, Ga., Mr. R. W. Whitehead, division plant superintendent, Chicago, and B. P. Hancock and J. P. Edwards, special agents, Atlanta, Ga., were recent New York visitors on company business.

Messrs. B. P. Hancock and J. P. Edwards, special agents, Atlanta, Ga., were recent business visitors to New York.

Mr. J. F. Nathan, commercial superintendent; Mr. S. M. Williams, manager of press service; John Simmonds, district commercial manager, and L. Wingate of the *World* office, New York, have gone to Chicago in connection with the work of the national Republican convention.

Mr. William McD. Milne, formerly of Denver, Col., is now division auditor with headquarters at Chicago, Ill.

Mr. J. W. Gaffney has been appointed district commercial manager of the first district, Eastern Division, with headquarters at New Haven, Conn.

Mr. J. B. Dillon of the Dallas, Tex., office has been promoted to be district wire chief and supervisor of equipment with headquarters at the same point. Mr. Dillon has had a wide experience in the telegraph service and is well fitted for his new duties.

Mr. W. H. Peterson, manager at Scranton, Pa., has been appointed assistant traffic supervisor at the same point. Mr. S. G. Smith, formerly manager at Williamsport, Pa., succeeds Mr. Peterson as manager at Scranton, and Mr. H. W. Eberly succeeds Mr. Smith at Williamsport.

At the annual meeting of the American Union Telegraph Company, held May 29, Messrs. G. W. E. Atkins, A. R. Brewer, B. Brooks, Newcomb Carlton, Geo. H. Fearons, A. G. Saylor and J. B. Van Every, were elected directors. Mr. Theo. N. Vail was elected president, Thos. F. Clark vice-president, Wm. H. Baker, secretary and A. R. Brewer treasurer.

The second meeting of the commercial managers of the sixth district, Western Division, was held at Indianapolis, Ind., May 24. The purpose of the meeting was for the exploitation of universal service, development of revenues, etc. Mr. A. A. Montgomery, district traffic superintendent, of Cincinnati, Ohio, was present and gave an instructive talk upon the subject of "Moving the Business." Telegrams were received from Mr. M. T. Cook, division commercial superintendent, and Mr. W. J. Lloyd, division traffic superintendent, Chicago, expressing regrets of their inability to attend and congratulating the field forces upon the splendid results attained. Among the managers present were: J. W. Miles, Lawrenceville, Ill.; F. B. Bradley, Mattoon, Ill.; J. S. Meador, Mt. Vernon, Ill.; H. K. Armstrong, Anderson, Ind.; J. R. Sample, Bedford, Ind.; J. E. Riley, Bloomington, Ind.; J. J. Lash, Columbus, Ind.; H. A. Hutton, Crawfordsville, Ind.; A. A. Burr, Evansville, Ind.; R. J. Hammond, Frankfort, Ind.; Z. M. Apple, French Lick, Ind.; P. L. Mounce, Indianapolis, Ind.; M. H. Hutton, Kokomo, Ind.; E. L. Dyer, Lafayette, Ind.; Chas. Massena, Logansport, Ind.; F. J. Rhorer, Marion, Ind.; W. E. Jarvis, Muncie, Ind.; W. A. Mossman, New Albany, Ind.; F. W. Booher, New Castle, Ind.; F. M. Andres, Peru, Ind.; J. P. Freeman, Richmond, Ind.; R. E. Scorah, Terre Haute, Ind.; R. H. Underwood, West Baden, Ind.; S. A. Rhodes, Bellefontaine, Ohio; J. H. Jarvis, Greenville, Ohio; W. W. Born, Kenton, Ohio; C. W. Mason, Marion, Ohio; C. E. Machir, Piqua, Ohio; G. W. Morton, Sidney, Ohio; Miss E. E. Martin, Tiffin, Ohio; M. A. Ryan, Urbana, Ohio.

Mr. J. S. Calvert, district superintendent, Richmond, Va., announces the following appointments of managers: J. L. Duffell at Abbeville, S. C., vice T. C. Greer; H. M. Armistead, former manager at Salisbury, N. C., at Raleigh, N. C., vice C. B. Wade, who leaves the service; E. C. Seagle at Rutherfordton, N. C., vice L. W. Bowden; C. N. Martin at Winston-Salem, N. C., vice D. F. Cason, resigned; Miss Alyce H. Alexander at Lexington, N. C., vice O. L. Patterson; Miss Lessie Snipes at Kershaw, S. C., vice G. P. McMillan, transferred to Newberry, S. C.; Miss E. P. Wood at Rocky Mount, N. C., vice Miss M. E. Riley; A. H. Nowell at Greensboro, N. C., vice John Shinberger, transferred to Roanoke, Va., vice J. F. Terrell appointed second district manager for the State of Virginia, with headquarters at Roanoke; W. A. Wentz at Chester, S. C., vice T. H. Chancellor; Miss Genevieve Moore at Monroe, N. C., vice Miss M. M. Pyron; Jerome Farmer at Gaffney, S. C., vice T. C. Parker; G. P. McMillan at Newberry, S. C., vice C. A. Murphy, transferred to Salisbury, N. C.; vice C. N. Martin, transferred to Winston-Salem as manager; Samuel Cain at Clinton, N. C., vice J. H. Carpenter, transferred to the managership at Washington, N. C., vice W. R. Staples; E. M. Canada, night chief operator at Norfolk, Va., has been promoted to the position of second district manager for the state of North Carolina, with headquarters at Raleigh, N. C.

The quarterly meeting of the Western Union Telegraph Company was held June 12. The statement for the quarter shows net earnings of $1,139,980, against $1,982,493 in the same quarter of 1911, and $1,950,000 for the same three months in 1910. After the payment of bond interest, amounting to $347,633, against $433,953 in 1911, dividends of $748,005, against $747,887 in the same quarter of the previous year, there remained a surplus for the quarter of $44,342, which compares with $800,653 in 1911. The gross earnings for the quarter amounted to $10,901,850 and total operating expenses, including depreciation and taxes, $9,761,870.

The Telephone.

Mr. P. H. Hopkins, commercial superintendent of the Mountain States Telephone and Telegraph Company, Salt Lake City, Utah, has resigned to accept the position of special agent in the office of F. L. Gilman, general manager of the Missouri, Kansas and Texas Railroad, at Kansas City, Mo.

Mr. D. H. Fitch, electrician of the Cazenovia, N. Y., telephone exchange, has resigned that position. Mr. Fitch, who is an old-time telegrapher and a member of the Society of the United States Military Telegraph Corps, established the Cazenovia exchange in 1894. He is a member of the Telephone Pioneers of America.

The New England Telephone and Telegraph Company has announced a new pension system which will go into effect on July 1. The minimum amount is $25 per month and the maximum $100 per month. After twenty years of service an employe of the company may be pensioned for disability at sixty; at sixty-five he may retire upon a pension at his own volition, and at seventy retirement is compulsory unless the board of directors decides to make an exception.

Ants Destroy Telephone Cables.—The lead covering and insulation of telephone cables in Austria are being attacked and destroyed by white ants. This trouble has been reported before from other countries.

Value of National Telephone Company's Property.—It is stated that the claim of the National Telephone Company against the British Post Office for the purchase of the telephone system amounts to $104,625,000.

Telephone Service in England.—The British Postmaster General stated, at the annual dinner of the London Chamber of Commerce, that in 50,000 telephone calls during the preceding six months, the average time between the ring and the answer was 5.1 seconds, and the average time used in making the desired connection was 28.6 seconds. This time compares very favorably with the American service as indicated in a recent statement by the New York Public Service Commission.

Telephone Herald.—Another trial of the plan for news distribution by telephone will soon be made in Philadelphia by a company which has been organized for this purpose. It is purposed to charge $1.50 a month to subscribers who will be supplied with all kinds of news through the day on a regular schedule, and with musical entertainments in the evening.

The New Jersey "Telephone Herald" which conducted a similar business in Newark, N. J., and failed last February, owing to lack of capital, has resumed business, having secured new capital.

The best way to keep posted in telegraphic and telephonic progress is to read TELEGRAPH AND TELEPHONE AGE. Subscription price $2 per year.

Radio-Telegraphy.

Wireless in Constantinople.—The Turkish government has decided to prohibit the use of wireless telegraphy by ships in the port of Constantinople.

Wireless at Carnegie Schools.—Students at the Carnegie Institute of Technology at Pittsburgh, Pa., have established a wireless station which it is stated, has an operating radius of 200 miles.

Telephone Extension in Fort Smith.—The Southwestern Telegraph and Telephone Company, has appropriated $45,000 for extensions and improvements to its plant in Ft. Smith, Ark.

Two Wireless Operators on Allan Steamers.—The Allan Royal Mail Line has arranged with the Marconi Wireless Telegraph Company, to carry two wireless operators on every ship of the Allan fleet.

Wireless Telephony.—It is stated that the Italian naval and military authorities have established wireless telephone communication between Monte Mario and Becco di Vela, on Madalena Island, a distance of about 160 miles.

German Wireless Regulations.—New official regulations, according to which all German passenger steamers carrying seventy-five or more persons, inclusive of the crew, must be equipped with wireless apparatus with a radius of 100 sea miles, will go into effect on October 1.

Wireless Telephones on Danish Steamers.—All Danish passenger steamers and ferryboats on the route between Sweden and Germany are to be equipped with wireless telephones. No operator is necessary. Twenty wireless telephone stations will be erected on the Danish, German, and Swedish coasts.

Wireless Telephony in France.—It is reported from Toulon, France, that remarkable success has attended the experiments in wireless telephony being conducted on the yacht "Hirondelle," belonging to Prince Albert of Monaco. It is said that the "Marsellaise" played at Algiers was registered and definitely heard aboard the "Hirondelle" lying off Toulon. M. de Lepel is the inventor of the apparatus used.

Wireless from Aeroplanes.—Wireless messages were successfully transmitted from an aeroplane in flight in tests recently made at Chartres, France. Mr. Rouzet of the Société Radio-Electricite, the inventor of the apparatus accompanied M. Frantz in his biplane on an extended flight and sent messages which were clearly recorded at a distance of thirty miles. The wireless apparatus complete weighs only seventy pounds.

Deferred Rate for Wireless Messages.—The Marconi Wireless Telegraph Company has instituted a deferred transatlantic service at eight cents per word. The rate for immediate service will hereafter be sixteen cents per word. All telegraph offices in the United Kingdom will cooperate with the Marconi system is this schedule,

Digitized by Google

and the Western Union Company will be the receiver and distributer in the United States and Canada.

Poulsen System of High-Speed Wireless Transmission.—An illustrated description of the stations and appliances for experimental high speed wireless transmission (Poulsen system) between Lyngby, Denmark, and Cullercoats, England, is given in the *Post Office Electrical Engineers' Journal* of London. A demonstration of the system at speeds of upwards of 200 words per minute was recently given across the 550 miles separating the two stations.

Wireless to French Possessions.—The French Government is considering a scheme for the establishment of a system of wireless telegraphy connecting with all the French Colonial possessions. The system would extend from Paris to Timbuctoo in the Sahara, to the Marquises Islands and to Martinique. All the French war vessels are to be equipped with outfits, and it is expected that all the large French steamship companies will follow the example.

Wireless Telephony for Russian Police.—Mr. Keller, an electrical engineer of Warsaw, Russia, has invented a system of wireless telephony whereby policemen on duty in the town can communicate with their stations without leaving their posts. The policeman carries the apparatus in his pocket and hangs it onto the wall of the nearest house when wanted. He then presses a button, which gives the signal at the nearest station. It is stated that the voice is very distinct.

Credit for Operator Cottam of the "Carpathia."—Inasmuch as Captain Rostron of the steamer "Carpathia," who rescued over 700 of the "Titanic's" passengers from life-boats, has been receiving honors and encomiums for his valor, it has been pointed out that wireless operator H. T. Cottam of that steamer is deserving of equal credit for his part in the rescue work. Had it not been for his attention to duty the results of the disaster probably would have been very different to what they were.

Connecting North and South America by Wireless.—The Marconi Wireless Telegraph Company of America has arranged to equip stations at New Orleans, at Swan Island in the Caribbean sea and at Santa Marta, Colombia, thus providing a direct wireless service between North and South America. The new stations are to be erected for the United Fruit Company. The Santa Marta station is well advanced and work on the other stations will be started in a few weeks. Mr. M. Musgrave, New Orleans, La., is superintendent of the electrical department of the Fruit Company.

Wireless at Sea.—Mr. H. Samuels, postmaster general of Great Britain states that all wireless telegraph installations on board British ships are capable of being used for inter-communication with other systems, and they are worked in accordance with licenses issued by the Post Office. The Radio-Telegraph Convention he said does not provide for the compulsory interchange of messages between ships for other than distress purposes, and the Marconi Company declined to intercommunicate, except in cases of distress, with ships fitted with other systems unless the matter had been arranged by agreement.

Wireless Telegraphy in Spain.—Some of the difficulties of obtaining a reliable ground connection for a wireless telegraph station may be obtained from the experience had at Santa Cruz, on the Island of Teneriffe. The ground there is practically volcanic lava and the climate very dry and in order to obtain good earth connection it was necessary to dig a trench 495 feet long and 6½ feet deep in which were buried sheets of galvanized iron. The guaranteed range of this station as well as that of the other three stations at Cadiz, Las Palmas and Barcelona, is about 110 miles.

Wireless During Eclipse of Sun.—Mr. W. H. Eccles of London, England, made some interesting wireless experiments during the eclipse of the sun on April 17. It has always been observed that the electric waves used in wireless telegraphy travel better during the times of darkness than in daylight; also that stray atmospheric discharges are propagated better in darkness than in light. Mr. Eccles' observations on the strength of signals and "strays" showed that the usual effect was produced, the signals and stray currents being intensified during the eclipse. Another feature brought out was the fact that during portions of time in the period of greatest darkness propagation was hindered.

New Marconi Stations on the New Jersey Coast.—The Marconi Wireless Telegraph Company of America has purchased 550 acres of land near Belmar, N. J., which it intends to use as a site for the erection of a high-power wireless station from which communication can be held direct with London. The price paid for the land was between $125,000 and $140,000 and it is expected that the cost of erecting the plant will reach $750,000. The company has also obtained an option on land at Tom's River on which it is planned to build a duplex station from which sending and receiving messages can be carried on at the same time. The new plant will be completed in June, 1913, and it will then be possible, it is claimed, to transmit a message to London by wireless in as short a time as by cable. Mr. Marconi will come to New York in September and will personally supervise the work of construction.

Mr. E. Reynolds, vice-president and auditor of the Postal Telegraph-Cable Company, of New York, writes: "It is with much pleasure that I renew my subscription for your excellent publication for another year. Without it I do not know how I should keep posted with regard to many matters of interest affecting our business."

Annual Convention of Association of Railway Telegraph Superintendents.

[The next convention will be held at St. Louis. Mo., May 20, 1913. Mr. J. B. Sheldon, of Omaha, Neb., is the new president.]

The thirty-first annual convention of the Association of Railway Telegraph Superintendents was called to order at 10:20 a. m., June 4, at the Waldorf-Astoria Hotel, New York, by President G. A. Cellar of Pittsburg, Pa. There was a large attendance of members at the opening exercises, and many ladies, the wives and daughters of the members.

Secretary P. W. Drew of Chicago read a letter from the American Telephone and Telegraph Company extending the courtesies of free telephone service, both local and long distance.

The following new members were then elected:

Active—C. G. Baird, manager telegraphs and telephones, Pennsylvania Railroad, New York; C. P. Dugan, superintendent of transportation, Norfolk and Southern, Norfolk, Va.; C. A. Worst, assistant superintendent of telegraph, Chicago, Burlington & Quincy, Chicago, Ill.; E. E. Backus, superintendent telegraph, El Paso and Southwestern, El Paso, Tex.; Robert H. Corson, telephone inspector, Erie Railroad, Jersey City, N. J.; C. H. Hubbell, superintendent telegraph, Chicago, Rock Island and Pacific, Chicago, Ill.; D. J. Kavanaugh, assistant general foreman, Illinois Central, Memphis, Tenn.; C. E. Marsh, chief clerk to general superintendent, Kansas City Terminal, Kansas City, Mo., and B. S. Jenkins, general superintendent telegraph, Western Lines, Canadian Pacific Railway, Winnipeg, Man.

Associate—B. S. Stewart and R. E. Green, Standard Underground Cable Company, Chicago, Ill.; C. S. Pflasterer, National Carbon Company, Cleveland, Ohio; H. T. Vaille, railroad agent, Mountain States Telephone and Telegraph Company, Denver, Col.; F. J. Lepreau, salesman, Thos. A. Edison, Inc., Chicago, Ill.; Wm. Henry Jaques, vice-president and general manager, United Telephone Company, Boston, Mass.; J. W. Young, Kerite Insulated Wire and Cable Company, New York; C. S. Rhoads, Jr., General Railway Equipment Company, New York; Claude L. Matthews, vice-president; W. N. Matthews and Bros., St. Louis Mo.; R. E. Chetwood, engineer of construction, Western Union Telegraph Company, New York.

President G. A. Cellar then read his annual address.

Mr. Cellar gave a comprehensive review of the affairs of the association in the past year and predicted a prosperity during the coming year beyond anything previously experienced by the association. He suggested the desirability of selecting a more favorable time for the annual meetings than the month of June, and the Reid memorial was referred to. "The railway telegraph superintendents," he said, "have a peculiar interest in anything connected with the memory of practically the first telegraph superintendent." He offered a warning as to the relations between the association and the Railway Telegraph and Telephone Appliance Association, and commended to the members the deep and careful study of the association's responsibilities in the matter of affiliation with the appliance association. A plan for conducting missionary work in an effort to encourage the membership of the association was suggested, and in closing, president Cellar extended his thanks to the various committees for their work in the interest of the association.

The reports of the secretary-treasurer, auditors and executive committee were then read. They showed the Association to be in a sound financial condition, and increasing in membership. There are 105 active members and 64 associate members of the association.

Mr. E. C. Keenan, chairman, read the report of the committee on wire crossings. The committee reported having held several meetings and drafted part of the specifications, but was unable to get them completed for submission at this meeting. It was suggested therefore that the committee continue the work. The proposed specifications refer to the

J. B. SHELDON, PRESIDENT.

construction and maintenance of aerial wires or cables of telephone, telegraph, signal and all other wires of similar character, crossing railroad rights of way, etc. The wires to be covered by the specifications are not to carry more than 550 volts.

The report of the committee on high tension wire crossings was read and on the recommendation of president Cellar, section 18 was amended with respect to the insulation of guy wires.

Mr. E. P. Griffith, chairman of the committee on the delivery of telegrams on trains, reported progress, and the committee was continued. Mr. Griffith also made the final report of the Turner Monument Fund Committee. He briefly reviewed the history of the movement and referred to the dedication on May 2, as reported in TELEGRAPH AND TELEPHONE AGE of May 16, closing with a financial statement of the disposition of the fund, which showed a balance of $735.15 on hand. Of this it was agreed to pay the sculptor, Mr. Charles Keck, of New York, an additional $500 for extra work on the tablet and monument, and the balance of $235 was appropriated to cover the expense of

Digitized by Google

producing a pamphlet giving a history of the movement which was so successfully terminated on May 2 in the dedication services at Harriman, N. Y.

The report of the committee on miscellaneous matters was next read by Mr. E. A. Chenery of St. Louis, chairman, on the subject of protection of poles against grass fires. The committee recommended clearing the ground of grass within a radius of five feet or more around the poles. Remarks on the subject were made by Messrs. W. W. Ryder, G. A. Dornberg and W. J. Camp. The raising of wires to escape moving buildings, etc., and the protection of linemen in handling wires were also subjects which received the committee's consideration.

Mr. L. M. Jones, chairman of the committee on standardization of rules governing the handling of train orders by telephone, stated that on account of the difficulty in securing a quorum, the committee had not been able to take any definite action. He therefore reported progress, and the committee was continued. Mr. L. B. Foley, representing the association on the James D. Reid Memorial Committee, made a few remarks on the subject.

At the afternoon session, secretary Drew read a letter from Mr. Belvidere Brooks, general manager of the Western Union Telegraph Company, extending the free use of that company's wires to the members and their families during the convention for social correspondence.

The paper of Mr. R. E. Chetwood, engineer of construction of the Western Union Telegraph Company, New York, on "Construction Materials and Methods," was read in abstract by the author, printed copies having been in the hands of the members for two weeks.

The paper brought out a very lengthy and interesting discussion which was participated in by Messrs. W. J. Camp, M. H. Clapp, J. C. Hubbard, Charles Selden, G. A. Dornberg, C. S. Rhoads, M. C. Allen and others.

Mr. Camp described in detail the practice and experience of the Canadian Pacific Railway's Telegraph in regard to the size of poles, spacing of wires on cross arms, insulators, underground service, etc. His road, he said, favored porcelain insulators, and he exhibited some samples of such insulators used on his company's lines. The Canadian Pacific Telegraph uses nothing but tile conduit for underground service. Double cross-arms, he stated, were required by the Canadian Pacific Railway Commission at crossings.

Mr. Drew called attention to some of the possible dangers of using short poles. The insulators made excellent targets for small boys with baseball proclivities, and he cited instances of much trouble on his lines from this cause.

A paper on "The Handling of Supplies" by Mr. W. G. Higgins, superintendent of supplies of the Western Union Telegraph Company, New York, having been previously distributed among the members, was read in abstract by the author and discussed by Messrs. E. A. Chenery, W. F. Williams and others.

Mr. Wm. Maver, Jr., of New York, closed the afternoon session with an interesting paper on "Some Notes on the Polarized Sounder in Telegraphy," and showed the instrument in actual operation.

WEDNESDAY'S SESSION.

The meeting was called to order at 10 a. m. by President Cellar, who introduced Mr. Belvidere Brooks, general manager of the Western Union Telegraph Company. Mr. Brooks greeted the members of the association and spoke of the amicable relations existing between the telegraph and railroad companies.

Mr. Angus S. Hibbard, executive department of the American Telephone and Telegraph Company, New York, was next introduced. He described the relations of the telephone and the telegraph in their practical operation. He stated that there were now over 300 joint telegraph and telephone offices in small towns, and very satisfactory service was being rendered. By this arrangement twenty-four-hour telegraph service was given where it would not pay to keep telegraph offices open continuously. He referred in detail to the methods of handling the service between the telegraph and the telephone, and pointed out the many advantages to the public therefrom.

A paper entitled "Telegraph and Telephone Facilities of the St. Louis Terminal" was then read by Mr. F. E. Bentley, superintendent of telegraph of the Terminal Railroad Association, St. Louis, Mo., and this was followed by a paper on "The Use of the Main Line Relay in Telephone Selector Operation," by W. W. Ryder, general superintendent of telegraph of the New York Central Lines, Chicago. A lengthy discussion took place on Mr. Ryder's paper, and was participated in by Mr. W. E. Harkness, V. T. Kissinger, Wm. Bennett, G. K. Heyer, W. L. Cook, W. J. Camp and L. M. Jones. These gentlemen related their experiences with main line relays in connection with the operation of selectors, and pointed out the advantages and disadvantages of this method of selector control.

The next paper read was one by Mr. W. N. Fashbaugh, traffic engineer of the Western Union Telegraph Company, New York, entitled "Telegraph Traffic." In the discussion, Mr. Charles Selden explained the method of handling traffic on his lines. Mr. E. C. Keenan referred to the traffic arrangements on his road. The telephone, he said, gave much quicker service than the telegraph and was in every way much more satisfactory. Mr. S. B. Haig referred to the work of the Western Union Telegraph Company in carrying out its plans for the improvement of traffic facilities, and pointed out that the personal interest of the operator was of the utmost importance. Mr. H. T. Vaille complimented the association on its telephone work.

THURSDAY'S SESSION.

President Cellar called the meeting to order promptly, and made a statement with reference to the proposed Reid memorial. For the enlightenment of the members as to the plan of the project, he distributed some copies of the pamphlet issued by the memorial general committee.

Digitized by Google

Mr. W. W. Ryder suggested the desirability of starting a campaign for the enlargement of the membership of the association, and moved that a membership committee of five be appointed. The motion was carried.

A paper entitled "What the Telephone Has Done for the Santa Fe Railway" was then read by Mr. L. M. Jones, of the Atchison, Topeka and Santa Fe Railway, Topeka, Kan. The paper was discussed by Messrs. Chas. Selden, F. T. Wilbur, W. J. Camp, W. W. Ryder and S. L. Van Akin, Jr.

The next paper was one by Mr. G. M. Yorke, engineer of the Western Union Telegraph Company, New York, on "The Maintenance of Telegraph Lines," and it was discussed by Messrs. E. A. Chenery, L. H. Beck, V. T. Kissinger, M. H. Clapp, G. A. Dornberg, M. C. Allen, W. J. Camp, E. C. Keenan and J. J. Ross.

Mr. J. F. Caskey of the Lehigh Valley Railroad, South Bethlehem, Pa., then presented a paper entitled "The Use of the Portable Telephone in Railroad Service."

At the afternoon session Messrs. G. C. Kinsman and J. S. Stevens, former superintendents of telegraph of the Wabash and of the Chesapeake and Ohio railroads, respectively, were elected honorary members of the association, in accordance with the rules.

The discussion of Mr. Caskey's paper read at the morning session was then taken up. Messrs. J. B. Sheldon, W. W. Ryder, W. J. Camp, S. L. Van Akin, Jr., W. C. Walstrum, J. J. Ross, C. A. Parker, Chas. Selden and E. A. Chenery gave some interesting facts regarding the use of portable telephones on their respective lines, and much information of value was brought out. Following the discussion on Mr. Caskey's paper. a paper on "Telegraph Line Maintenance" was read by Mr. W. S. Melton of the "Queen and Crescent Route," Danville, Ky., and discussed by Messrs. J. J. Ross and F. J. Howe.

The committee on resolutions then made its report tendering the thanks of the association for courtesies extended by the New York Telephone Company, the Railway Telegraph and Telephone Appliance Association, the Western Union Telegraph Company, Mr. Belvidere Brooks personally and others who contributed toward the entertainment of the association.

Memorial resolutions were also passed on the deaths of the late I. T. Dyer of the San Pedro, Los Angeles and Salt Lake Railroad, Los Angeles, Cal., former president of the association, and J. G. Jennings of the Chicago, Rock Island and Pacific Railroad, Chicago.

A communication was read from Mr. James Kent, manager of the Canadian Pacific Railway's Telegraph, Montreal, Que., giving an account of an interesting experience in the use of dry batteries at Sudbury, Ont., during a flood which submerged the storage battery. Dry batteries were pressed into service to supply energy for the operation of several circuits, including duplexes and quadruplexes, with very satisfactory results.

A meeting of the executive committee was then held, after which the following named officers were elected: President, J. B. Sheldon, Union Pacific Railway, Omaha, Neb.; vice-president, Wm. Bennett, Chicago and North Western Railroad, Chicago; second vice-president, A. B. Taylor, New York Central Lines, New York; secretary and treasurer, P. W. Drew, Minneapolis, St. Paul and Sault Ste. Marie Railway, Chicago. The new officers were then duly installed, after which St. Louis, Mo., was selected as the place of the next annual convention, May 20, 1913, being fixed as the date.

A resolution was passed thanking the committee on topics for their work in securing so many excellent papers, and then at 5:20 p. m. the convention adjourned.

ENTERTAINMENT.

On Monday evening an informal reception was held in the East Room at the Waldorf-Astoria Hotel.

Tuesday morning the ladies spent in shopping and sightseeing, and in the afternoon they were taken on an automobile sight-seeing ride around the city. In the evening the entire party, through the courtesy of the New York Telephone Company, attended the Comedy Theatre, where they witnessed the play, "When Bunty Pulls the Strings."

Wednesday morning the ladies were free to spend the time as suited their fancy, and were kept busy shopping, sightseeing and indulging in other forms of entertainment.

Mr. Angus S. Hibbard, of the executive department of the American Telephone and Telegraph Company, entertained about 50 of the members at luncheon in the café of the Waldorf-Astoria after adjournment on Wednesday. It was entirely informal and a very enjoyable affair.

At 2 o'clock the men left the hotel in Fifth Avenue motor buses, and were conveyed to the Spring exchange of the New York Telephone Company, where they spent an hour inspecting this modern telephone establishment. At 3 p. m. they resumed the bus trip and were taken to the Western Union headquarters at 195 Broadway, which they also inspected, and at 4.30 o'clock they were conveyed to Pier 1, North River, where they boarded a steamboat for Coney Island. At this famous resort they were tendered a shore dinner at Feltman's, after which they were let loose to enjoy themselves. Most of the party returned to New York by rail.

Owing to the rain on Thursday afternoon, the scheduled trip around Manhattan Island on a sightseeing yacht for the ladies was abandoned. A theatre party was made up instead, and the ladies attended the Lyceum Theatre on Forty-fifth Street. In the evening, the entire party attended the Winter Garden at Broadway and Fiftieth Street.

On Friday, the party visited the Edison Works at West Orange, N. J., and after an inspection of the plant, luncheon was served through the courtesy of Mr. T. A. Edison. Everyone was delighted with the hearty reception accorded by Mr. Edison. A moving picture of the 275 visitors was taken, and shortly afterward shown on the screen to the amusement of all. A group picture of the entire party was also taken, and copies will be distributed among the members, with compliments

Digitized by Google

of Mr. Edison. An up-to-date phonograph entertainment and picture show was enjoyed by the visitors for about two hours in Mr. Edison's spacious library. The trip was made to West Orange over the Erie Railroad by special train, and the visitors returned in the afternoon.

The Banquet.

The banquet on Friday night at Martin's, Broadway and Forty-second street, was a fitting conclusion to the highly successful convention, and was an event that will long linger in the memory of those who participated. The large banquet hall was brilliant and fascinating in its illumination and decorations and the charm of the scene was greatly enhanced by the presence of the wives and daughters of many of the members.

It was 7:30 when toastmaster G. A. Cellar rapped for all to be seated, and a good deal of merriment was indulged in during the meal. The dinner was an excellent one and was favorably commented upon, and the service was all that could be desired, notwithstanding the general strike disturbances among the waiters in New York. An orchestra rendered superior music, and the more enthusiastic spirits joined in singing the popular airs in accompaniment. Mr. Cellar made an excellent toastmaster and his remarks in introducing the various speakers were happy and well chosen.

Mr. W. J. Dealy responded to the toast "The Ladies," and Mr. Charles Selden spoke for "The Association." Mr. Selden told the story of the origin of the association, its development and its work.

Mr. F. H. Bethell spoke for "The Telephone" and Mr. Belvidere Brooks for "The Telegraph." Mr. Brooks gave some interesting statistics, and in closing proposed a toast to president Theo. N. Vail, which was drunk by all present.

Mr. P. W. Drew, secretary of the association, stated that while he had been secretary he had served the interest of the association with thirty different presidents.

At the close of the exercises the musicians moved to the small ball room adjoining the banquet hall and dancing was enjoyed by a number of the guests.

The entertainment committee deserve great credit for the excellent manner in which they planned and carried out the entertainment features of the convention. The committee consisted of L. S. Wells, Long Island Railroad; L. B. Foley, Lackawanna Railroad; E. P. Griffith, Erie Railroad; J. C. Johnson, Pennsylvania Railroad; A. P. Eckert, National India Rubber Company; W. E. Harkness, General Railway Equipment Company; E. E. Hudson, Thomas A. Edison, Inc.; A. D. Walters, New York Telephone Company; and R. A. Patterson, C. F. Massey Company.

These gentlemen gave much time and thought to the arrangements and as a recompense they have the satisfaction of knowing that their efforts were highly successful and fully appreciated by all concerned.

NOTES.

In place of the time-honored convention badges a neat lapel button was substituted. The central portion was white enamel across which was shown a pole-line in gilt, and around this was a blue band, also of enamel, containing the name of the association in gilt letters.

The following-named ladies constituted the ladies' reception committee and they performed their duties in a very satisfactory manner: Mrs. C. H. Bristol, Mrs. J. F. Caskey, Mrs. A. P. Eckert, Miss M. Eckert, Mrs. K. W. Endres, Mrs. L. B. Foley, Mrs. J. J. Ghegan, Mrs. E. P. Griffith, Mrs. W. E. Harkness, Mrs. G. K. Heyer, Mrs. B. A. Kaiser, Miss T. Kaiser, Mrs. Wm. Maver, Jr., Mrs. L. S. Wells, Mrs. R. A. Patterson, Mrs. Charles Selden, Mrs. N. E. Smith, Mrs. J. B. Taltavall, Mrs. A. B. Taylor, Mrs. A. D. Walters.

Mr. J. J. Ghegan, president of J. H. Bunnell and Company, New York, exhibited one of the new "C Q A" relays and called attention to the new features of the instrument. In the magnet adjustment the magnets are instantly moved any desired distance from the armature. The armature tension spring adjustment is also simplified and improved. The relay is mounted on slate instead of wood, and is furnished with the Western Union clamp connections. Mr. Ghegan also distributed souvenirs in the shape of memorandum books with celluloid covers.

The General Railway Equipment Company, the consolidation of several important electrical manufacturing concerns which was announced recently in these pages, had a limited exhibit of specialties in its rooms in the Waldorf-Astoria. The principal feature was the dictograph and the Turner interior telephone. The dictograph installation was arranged in much the same manner as used by detective William J. Burns in the grafting and dynamite cases throughout the country in securing evidence. The Turner interior telephone permits of instant communication with the desired office without the interposition of a switchboard operator. Besides these there were shown the Egry train order register as used on the Chicago Great Western Railway; a newly designed operator's desk telephone set with jointed arm and a transmitter head box remarkable for simplicity of design and accessibility for renewal of cord connections. This is designed to be used with the head-band receiver, leaving both hands free. A three-drop blocking set in metallic case was also exhibited.

The following named manufacturing and operating concerns were represented at the convention. Some of these representives also hold membership in the associate list of the Association of Railway Telegraph Superintendents: American Telephone & Telegraph Company—Angus S. Hibbard, Henry Homer, B. A. Kaiser, Elam Miller, G. W. Peck. L. S. Brach Supply Company.

ATTENDANCE.

Among those present were:

Altoona, Pa.—J. H. Ditch, chief telephone inspector, Pennsylvania, and wife.

Atlanta, Ga.—L. H. Beck, division plant superintendent, Western Union Telegraph Company.

Aurora, Ill.—C. A. Worst, assistant superintendent telegraph, Chicago, Burlington & Quincy.

Baltimore, Md.—Chas. Selden, superintendent telegraph and general inspector transportation, Baltimore & Ohio, wife, and Miss Imogen Selden.

Boston, Mass.—A. C. O'Brien, telephone inspector, Boston & Maine; S. A. D. Forristall, superintendent telegraph, Boston & Maine, and wife; A. A. Bullens; T. P. Brennan.

Battle Creek, Mich.—E. D. Hubbard, general foreman telegraph, Grand Trunk, and wife.

Bloomington, Ill.—T. M. Haston, superintendent telegraph, Chicago and Alton.

Bradford, Pa.—J. E. Golden, superintendent telegraph, The Tide Water Pipe Company, Ltd.

Buffalo, N. Y.—G. W. Swan.

Chicago, Ill.—G. O. Perkins, superintendent telegraph, Chicago Great Western; P. W. Drew, superintendent telegraph, Minneapolis, St. Paul and Sault Ste Marie, and wife; Wm. Bennett, superintendent telegraph, Chicago and Northwestern Railway, and wife; Miss Margaret Bennett; C. H. Hubbell, superintendent telegraph, Chicago, Rock Island and Pacific, and wife; F. H. Van Etten, superintendent telegraph, Chicago, Terre Haute & Southern, and wife; W. W. Ryder, general superintendent telegraph, New York Central Lines, and wife; W. W. Ryder, Jr.; V. T. Kissinger, superintendent telegraph, Chicago, Burlington & Quincy, wife, and Mrs. Cornish; F. T. Wilbur, superintendent telegraph, Illinois Central, and wife; A. G. Francis; Archibald Wray; G. A. Jorg; John R. Hastie; W. L. Cook and wife; W. T. Kyle; B. K. Winchell, Jr.; G. H. Groce; E. V. Adams; John H. Finley and wife; R. W. Whitehead and wife.

Chester, Pa.—G. P. Fondersmith; Jesse P. Brundage.

Cleveland, Ohio.—E. C. Keenan, superintendent telegraph, Lake Shore & Michigan Southern, and wife.

Columbus, Ohio—G. A. Dornberg, chief lineman, Pennsylvania Lines West.

Denver, Col.—C. A. Parker, superintendent telegraph, Denver, Northwestern & Pacific, wife, and Miss Irene Parker; Howard T. Vaille.

Detroit, Mich.—J. J. Ross, superntendent telegraph, Michigan Central.

Denison, Tex.—W. H. Hall, superintendent telegraph, Missouri, Kansas and Texas.

Danville, Ky.—W. S. Melton, superintendent telegraph, Queen and Crescent.

Fremont, Ohio—E. L. Marshall.

Gibson, Ind.—W. L. Connelly, superintendent telegraph, Chicago, Indiana and Southern.

Indianapolis, Ind.—C. S. Rhoads, superintendent telegraph, Big Four.

Kansas City, Mo.—C. E. Marsh, chief clerk to general superintendent Kansas City Terminal Railway, and wife.

Lincoln, Neb.—H. A. Vaughan, assistant superintendent telegraph, Chicago, Burlington & Quincy, and wife.

Louisville, Ky.—R. R. Hobbs, Louisville and Nashville.

Montreal, Canada—Thos. Rodger, inspector telephones, Grand Trunk, and wife; W. J. Camp, assistant manager, telegraphs, Canadian Pacific; A. Dwight Smith.

Memphis, Tenn.—B. Weeks, superintendent telegraph, Illinois Central; D. J. Kavanaugh, assistant

Digitized by Google

general foreman, Illinois Central; J. B. Weitz.

Minneapolis, Minn.—L. H. Merrill and wife.

New Haven, Conn.—N. E. Smith, superintendent telegraph, New York, New Haven and Hartford, and wife; H. A. Shepard, assistant superintendent telegraph, New York, New Haven and Hartford.

Newark, N. J.—H. B. Fenn.

New York—Frank H. Bethell; T. W. Carroll; W. J. Dealy; Miss Lita Dealy; E. Y. Gallaher; H. E. Roberts; Miss Leone Roberts; J. C. Willever and wife; C. G. Baird, manager telegraphs and telephones, Pennsylvania Railroad, and wife; R. H. Corson, telephone inspector, Erie Railroad; L. B. Foley, superintendent of telegraph, Lackawanna, and wife; E. P. Griffith, superintendent of telegraph, Erie, and wife; Miss Gertrude M. Griffith, Miss Lura H. Griffith; A. B. Taylor, superintendent telegraph, New York Central and Hudson River, and wife; L. S. Wells, superintendent of telegraph, Long Island, and wife; C. H. Gaffney; C. H. Bristol and wife; Mrs. Clara Bristol Drakeford; Wm. Maver, Jr., and wife; Miss Effie Maver, Miss Jessie Maver; J. B. Taltavall and wife; Miss Florence J. Taltavall; Thos. R. Taltavall; J. J. Ghegan and wife; Miss Helen Ghegan; C. K. Heyer and wife; W. E. Harkness and wife; E. E. Hudson and wife; D. C. Keefe and wife; B. A. Kaiser and wife; Miss T. Kaiser, Percy N. Miller and wife; R. J. Murphy and wife; John F. Skirrow and wife; Minor M. Davis; R. J. Weeks and wife; Belvidere Brooks and wife; A. G. Saylor and wife; C. E. Kleinschmidt; A. G. Brach and wife; Leon H. C. Brach and wife; H. E. Gifford, Jr.; H. P. Kimball; R. G. Harris; E. W. Brown; F. V. McGinnesse; H. G. Thompson; W. F. Crowell and wife; A. D. Walters; R. S. Scarburgh; Henry Homer; E. Miller; R. E. Chetwood; M. C. Allen; W. N. Fashbaugh and wife; G. M. Yorke; J. F. Nathan; E. R. Harris; E. Whitmare and wife; A. D. Morrow; J. W. Young; Joseph A. Reator; R. D. Brixey; L. G. Martin; Francis J. White; J. Delmar Underhill; W. G. Hovey; D. D. Miller; P. M. Rainey; R. F. Spanier and wife; Robert G. Rish; J. E. Enders; Gregory Brown; John H. Bell; E. A. Hankins; R. N. Hill; John B. Harlow; J. G. Hackley; Rudolph R. Rosa; S. N. Rockwell; A. P. Eckert and wife; Miss H. Eckert; Miss M. Eckert; J. W. McDowell; Chas. N. Sigison; J. W. Barney and wife; E. R. Gill and wife; J. G. Moore; H. E. Merrell and wife; R. A. Paterson and wife; J. W. White; Chas. V. Drew and wife; W. Dodd and wife; W. M. Kinel; Wm. Marshall; C. O. Fountain; W. I. Capen; E. M. Mulford and wife; Miss Marjorie S. Mulford; J. A. Hill.

Omaha, Neb.—J. B. Sheldon, superintendent telegraph, Union Pacific, and wife.

Philadelphia, Pa.—J. H. McDonald, chief clerk, Pennsylvania.

Pittsburg, Pa.—L. A. Lee, superintendent telegraph, Pittsburg and Lake Erie; G. A. Cellar, superintendent telegraph, Pennsylvania Lines, West.

Portsmouth, Va.—W. F. Williams, superintendent telegraph, Seaboard Air Line, and wife; Miss Emma W. Williams and Miss Irma Falgham.

Richmond, Va.—Chas. W. Bradley, superintendent telegraph, Chesapeake and Ohio; T. R. Gooch, chief operator, Richmond, Fredericksburg and Potomac, and wife.

Reading, Pa.—C. M. Lewis, superintendent telegraph, Philadelphia & Reading.

Roanoke, Va.—W. C. Walstrum, superintendent telegraph, Norfolk and Western; Miss Margaret Walstrum.

Rochester, N. Y.—M. F. Geer; R. C. Leake.

St. Albans, Vt.—M. Magiff, superintendent telegraph, Central Vermont, and wife.

San Francisco, Cal.—E. F. Raymond, assistant superintendent telegraph, Southern Pacific Co.

St. Louis, Mo.—E. A. Chenery, superintendent telegraph, Missouri Pacific, and wife; F. E. Bentley, superintendent telegraph, Terminal Railroad Association of St. Louis, and wife; Claude L. Matthews.

South Bethlehem, Pa.—J. F. Caskey, superintendent telegraph, Lehigh Valley, and wife.

Springfield, Mo.—J. H. Brennan, assistant superintendent telegraph, St. Louis & Santa Fe.; H. D. Teed, superintendent telegraph, 'Frisco; Miss Mable Smith.

Syracuse, N. Y.—S. L. Van Akin, Jr., assistant superintendent telegraph, New York Central & Hudson River, wife and son.

St. Paul, Minn.—M. H. Clapp, superintendent telegraph, Northern Pacific, and wife; Mrs. Nelly J. Tidby, official stenographer.

Sandwich, Ills.—C. S. Rhoads, Jr.; E. C. Hennis.

Topeka, Kan.—L. M. Jones, superintendent telegraph, Atchison, Topeka and Santa Fe, and wife.

Toronto, Canada.—W. Marshall, superintendent, Canadian Pacific and wife; G. T. Rooke, inspector of transportation, Canadian Pacific, and wife.

Warwick, N. Y.—F. S. Work, chief dispatcher, Lehigh & Hudson River, and wife.

Washington, D. C.—W. H. Potter, superintendent telegraph, Southern Railway Co.

Wilmington, N. C.—W. P. Cline, superintendent telegraph, Atlantic Coast Line.

Railway Telegraph and Telephone Appliance Association.

At a meeting of the Railway Telegraph and Telephone Appliance Association held in New York during the convention of the Association of Railway Telegraph Superintendents, Mr. J. J. Ghegan, president J. H. Bunnell & Company, New York, was elected chairman; E. E. Hudson, of Thomas A. Edison Inc., West Orange, N. J., vice chairman, and W. E. Harkness, of the General Railway Equipment Company, New York, secretary and treasurer.

Mr. Charles Keck, sculptor, of New York City, in remitting to cover his subscription for another year, writes: "I am very much interested in following up the news of the telegraph and your paper gives me the latest information on these points."

CHANGES OF ADDRESS.—In ordering a change of address the old as well as the new address must be given.
REMITTANCES to Telegraph and Telephone Age should be made invariably by draft on New York, postal or express money-order, and never by cash loosely enclosed in an envelope. By the latter method money is liable to be lost, and if so remitted is at the risk of the sender.

June 16, 1912.

The Railway Telegraph Superintendents' Convention.

All concerned agree that the convention of the Association of Railway Telegraph Superintendents in New York, June 4, 5, 6 and 7, was in every respect the most successful ever held by the association. The attendance was the largest; the business sessions of the most profitable character and the entertainment was perfect as far as the combined wisdom of the entertainment committee could make it. Only once was it necessary to depart from the programme on account of circumstances over which the committee had no control. Rain compelled the substitution of an indoor entertainment for an outdoor trip for the ladies one afternoon; otherwise the weather was delightful.

It was gratifying to the officers of the association to be able to announce that in point of attendance it was the largest convention ever held by the association, two hundred and eighty persons being registered.

The entertainment was of a varied character and highly enjoyed by all, and the entertainment committee is to be congratulated on the success of its work. The banquet of course was the crowning feature of this highly enjoyable meeting and it is difficult to express in words the charm and success of this function. The arrangements were perfect and nothing occurred to mar the harmony and enjoyment of the occasion.

The papers read at the convention were of an unusually high class and on most appropriate subjects. The central thought in all was system, standardization, co-operation and intelligence, and it is safe to assert that everyone present at the meetings received some new ideas and many suggestions that will express themselves in concrete form when the superintendents have had time to formulate their plans for the improvement of the telephone (or telegraph) service along their respective lines.

The interest taken in the various papers by the members was evidenced by the extended discussions that took place, and the sum total of the proceedings will form a valuable text book on the art of telegraph and telephone construction and equipment for railroad service. A most important effect of the papers will be the promotion of harmony between the telegraph and railroads through these contributions. Such a meeting as this was cannot fail to lead to a better understanding between the two allied interests and draw them closer together.

The success of any enterprise is measured by the resulting benefits and it is safe to state that this meeting will, in this respect, establish a high standard.

The Telegraph and the Telephone.

Although the telegraph and the telephone are so closely related as to their nature and the service rendered there is a sharp line of distinction between them in their operation and management. When a person desires to send a telephone message he does the transmitting himself, the company merely supplies him with the facilities for carrying on his conversation; whereas in the case of a telegram he places the burden of the work upon the telegraph company, which maintains a large force of expert operators, clerks and bookkeepers for the purpose. Therein lies the chief point of difference in the character of the two services.

When a telegram is handed over to a telegraph company for transmission it is in many cases handled by twenty different persons before it reaches the person to whom it is addressed. It is interesting to trace the course of such a message. Let us assume that a business man in New York wishes to send a telegram to a person in a small town in Indiana. He rings the call box for a messenger, who carries the message to a branch office. From there it is transmitted to the main office, there passing through five hands before it reaches the Chicago wire for retransmission. At Chicago it is transferred to a local wire, after passing through five other hands and sent to, say, Lafayette, Ind., where it is again retransmitted over, say, a railroad wire to its destination. There it passes through the final stages of its progress and after being received by the operator, it is turned over to a clerk who in turn passes it over to a messenger for delivery. This is not an exaggerated case; it happens thousands of times every day, and it is presented simply to show the vast extent of the facilities a telegraph company must provide to handle public business. It must maintain this large force of employes whether a message passes through two hands or twenty. All of this means great expense to the telegraph companies, and the high degree of accuracy of the service is a splendid tribute to the care exercised by the companies in handling public's business.

A telephone dispatch between the same points

Digitized by Google

is not handled at all by any of the company's employes; the duties of the latter are simply to provide a path for the message.

A curious fact in this connection is that when a person uses the long distance telephone service he in one sense does the work himself and at the same time pays more money for the privilege; whereas, when he sends a telegram he makes the telegraph company do the work and pays less money.

From the foregoing, therefore, it can readily be seen that in respect to operation it is not so easy to compare the telegraph and the telephone as it would seem. The object of both services is the conveying of intelligence at a distance by electricity, but the methods employed are vastly different.

Senate Report on "Titanic" Disaster.

The report of the United States Senate Committee which investigated the circumstances attending the loss of the steamer "Titanic," on April 15, has reported its findings. It makes several observations and recommendations in regard to the wireless service and refers in pointed language to the failure of the operator on the steamer "Carpathia" to transmit a message of the disaster filed soon after the rescue of the survivors. The committee does not believe that the wireless operator on the "Carpathia" was duly vigilant in handling his messages after the accident. The recommendation is made, with Mr. Marconi's concurrence, that the practice of permitting the private sale of news stories by wireless operators be discontinued. Captain Smith of the "Titanic," who lost his life, is severely censured for not giving the proper alarm to the endangered passengers before he ordered the wireless operator to send out a distress message.

The report states that the steamer "Californian" was less than nineteen miles distant from the "Titanic," and that her officers and crew saw the distress signals of the latter steamer but failed to respond. It characterizes the conduct of those on the "Californian" as reprehensible and places upon the commander of that steamer a grave responsibility.

Tributes to the valor of J. G. Phillips, and Harold Bride, the wireless operators on the "Titanic" are paid by Senator Smith. The report says that "had not the under-paid wireless operator on the 'Carpathia' prepared for bed with his receiver still on his head, the 'Titanic' distress signals never would have been received by the rescuing ship.

Among the provisions of the bill introduced by Senator Smith are that after July 1, 1912, every vessel carrying more than fifty passengers must be equipped with wireless apparatus capable of transmitting and receiving messages at a distance of at least 100 miles day or night. Auxiliary power must be supplied independent of the main electrical power plant and two skilled operators are required.

A resolution giving the thanks of Congress to Captain Rostron of the "Carpathia" and his officers and crew for their courageous and effective rescue was adopted. It also provides $1,000 for a gold medal for Captain Rostron. Captain Rostron was also presented with a gold watch by some of the survivors of the "Titanic" whom he rescued.

Western Union Shirt Waists.—The recent order posted on the bulletin board at Western Union headquarters, New York, respecting the wearing of shirt waists, collars and sleeves of a certain style by the office girls has greatly excited the funny men and cartoonists of the daily newspapers. Their imagination is running wild, and what was intended to be an inoffensive requirement has been magnified and distorted by these alleged jesters to the proportions of an international episode. Some of the papers have gone so far as to illustrate fancy costumes of a great variety which the office girls are supposed to be required to wear. Evidently the newspaper clowns are having the time of their lives.

Society of the U. S. Military Telegraph Corps.

Following is a copy of a letter sent by David Homer Bates, New York Secretary of the Society of the United States Military Telegraph Corps, to each member of the legislative committee of the society:

"New York, May 24, 1912.

"Honorable Porter J. McCumber,
Chairman Pensions Committee, U. S. Senate,
Washington, D. C.

"Dear Sir:—Now that the Sherwood-Smoot bill has become a law, the members of the United States Telegraph Corps greatly hope your Committee will report favorably without further delay above bill for our relief.

"The official reports of Secretary Stanton, Generals Grant, Sherman, Rosecrans, and others, certify to the unique and valuable service of our corps. In fact the history of the civil war was largely recorded by the telegraph, which Stanton called his 'right arm.' Senator Scott of West Virginia, in a speech to the Senate, February 8, 1906, said: 'The military telegraph came under the immediate direction of President Lincoln as commander-in-chief through the secretary of war. The movements of the armies, the secrets of the nation, were entrusted to them, and yet not one was ever known to betray that knowledge and confidence in the most remote degree.'

"For forty years we have been appealing to Congress for the honor and justice so generously accorded to millions of soldiers in the United States Army, of which we formed an integral part, as established by the provisions of the Act of Congress approved by Grover Cleveland, January 26, 1897.

"Less than 250 of our corps survive. Pray do not let us die without this long-delayed recognition of our rights.

"Yours very truly,
"D. H. BATES, Secretary."

Course of Instruction in the Elements of Technical Telegraphy—XVII.

(*Copyrighted.*)

(*Continued from page* 341, *June* 1.)

[We began in our issue for October 16, 1911, the publication of a course of instruction in technical telegraphy. The course is published for the benefit of those of our readers who desire to fit themselves for better positions in their vocation. It is elementary throughout and is divided into chapters, following one another in logical order.

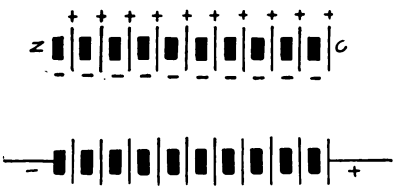
The course has received the hearty commendation of telegraph officials and experts for its scope and accuracy and its sound practicability. In each chapter examples will be given in order to illustrate the application of the rules to practical cases, and each chapter will be followed by a series of questions pertaining to the subject of the chapter, to be worked out by the student in order to review his progress.]

Battery Arrangement.

In drawings the positive pole of a battery is represented by the sign +, the negative pole by the sign —, and the battery itself by thin and thick strokes as in Fig. 5, where the thin strokes represent the coppers, and the thick ones the zincs.

The cells of a battery may be joined in series or parallel.

A battery in series means that the copper of one cell is joined to the zinc of the adjacent one



FIGS. 5 AND 6.—CONVENTIONAL REPRESENTATIONS OF BATTERIES.

throughout the length of the battery, as in Fig. 6.

A battery connected in parallel means that it is divided into two or more sets, the cells in each set being in series, but the end coppers and zincs of each set joined together. Fig. 7 shows a battery of two sets connected in parallel.

Now let us see how these different arrangements affect the current strength.

In the series method each copper being joined to its adjacent zinc the electromotive force (written E. M. F.) of one cell is added to that of the next, the total E. M. F. being the E. M. F. of all the cells added together.

In the same way, as each cell offers a certain amount of resistance to the current, the total internal resistance of the battery is the sum of the separate cell resistances.

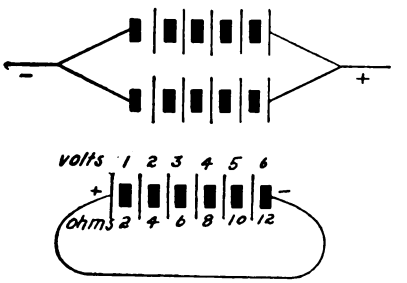
Take six gravity cells (Fig. 8), each with a resistance of 2 ohms, and E. M. F. of 1 volt. Place the battery on short circuit by joining the two end leads, as in the drawing, then the only resistance in circuit is the internal resistance of the battery, the resistance of the connecting wires being neglected.

To find the current, $\frac{E}{R} = I$, or $\frac{6}{12}$ = .5 ampere.

Double the number of cells and there will be no increase of current, for the internal resistance will also be doubled, and $\frac{E}{R} = \frac{12}{24}$ = .5 ampere as before. You might have 1000 cells and the current would still be the same as from 1 cell, as long as there is no external resistance.

Now divide the six cells into 2 sets of 3 cells each and connect them in parallel, as in Fig. 9.

As each cell has 2 ohms resistance, each set has a resistance of 6 ohms; but as the two sets are in

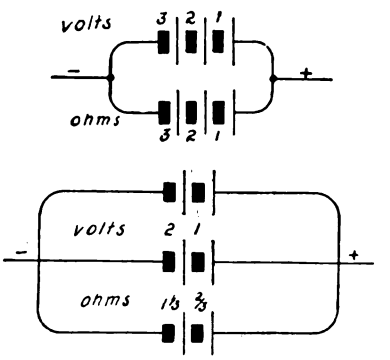


FIGS. 7 AND 8.—BATTERIES IN MULTIPLE AND SERIES.

parallel, the joint resistance is one-half of one set, or 3 ohms.

The E. M. F. is 3 volts, the circuit resistance 3 ohms, the current is therefore $\frac{E}{R}$ or $\frac{3}{3}$ = 1 ampere.

In this arrangement of cells the E. M. F. is one-half the E. M. F. in series, but the resistance is



FIGS. 9 AND 10.—SERIES-PARALLEL ARRANGEMENTS OF BATTERIES.

only one-fourth; consequently the current strength is doubled.

Now divide the six cells into 3 sets of 2 cells

Since there are only two cells in each set the E. M. F. is only 2 volts. The resistance in each set is 4 ohms, and the joint resistance 1⅓ ohms. The current is therefore 2 ÷ 1⅓ = 1.5 ampere.

Digitized by Google

Here the E. M. F. is one-third the E. M. F. in series, but the resistance is only one-ninth; the current is consequently three times stronger.

(*To be continued.*)

QUESTIONS TO BE ANSWERED.

[One of the most effective means of imparting information is to ask and answer questions, the value and power of this method being due to the fact that the information given in an answer is specific and direct. Asking questions for the student to answer for himself has proved to be an excellent means of education, as it promotes and encourages concentration of thought and investigation in order to arrive at the correct answer. "Electrical Instruments and Testing," by Norman H. Schneider, with chapters on testing wires and cables and locating faults, by Jesse Hargrave, a well-known and capable electrical engineer, is now being covered in this department. These subjects will no doubt prove of great interest to students, as they are timely and important, and each student should have a copy of the book at hand in order to follow intelligently the study of the subjects under consideration.]

What is the advantage of mounting the coil on pivots?

Name the various types of Weston voltmeters.

What is the sensibility of the Weston portable voltmeter?

How is the sensibility of the Weston portable direct-current voltmeter increased?

How much resistance per volt is added for sensibility in the other types of switchboard voltmeters?

What percentage of the total energy is necessary to operate the Weston switchboard voltmeter?

What temperatures are most switchboard instruments calibrated for?

For a change of temperature between 100 deg. and 80 deg. F., what does the instrument error amount to?

What is the effect on the coil of the instrument of an increase or decrease in the temperature?

What are duplex indicating instruments?

For what classes of work are duplex instruments suitable, and why?

What is the effect on indicating instruments of poor connections?

What is a potential indicator?

How is the scale reading of a potential indicator kept within limits?

Does the needle move at once when the circuit is closed?

Referring to Fig. 38, in the book, how are the two scales read?

What is a differential voltmeter and how is it used?

When connected to two generators what do the readings of the differential voltmeter indicate?

Why are indicating instruments provided with double scales?

What is a multiplier?

What are multipliers used for and how are they connected in circuit?

Why is the adjustment of a multiplier not suitable for all voltmeters?

With a six-volt voltmeter of 521 ohms resistance and a multiplier with a value of ten, what resistance would it measure?

Why are multipliers of great utility?

What is the meaning of the prefix "milli"?

What is a millivolt?

What is a milliampere?

What are millivoltmeters and milliammeters principally used for?

The Phillips' Memorial.

In our issue for May 16 we referred to the appointment of a committee by the Maritime Exchange of the Port of New York to receive subscriptions not only for a memorial to the late "Jack" Phillips, the wireless operator on the "Titanic," but for a permanent fund for the benefit of wireless operators in the future. It is known as the "Marine Wireless Operators' Fund" and subscriptions are solicited for the purposes outlined. Contributions are rapidly coming in and the total amount so far received is close on to $2,000. Through the information published in these columns May 16 considerable interest has been taken in this project by the telegraph fraternity in general.

Mr. R. W. A. Horner, chief operator of the Western Union Telegraph Company at Lynchburg, Va., has forwarded to us $3.15 contributed by the operating staff of that office toward the fund. Mr. Horner writes:

"We have all read with interest, and satisfaction, Mr. Harold Bride's thrilling narrative of Phillips' great work of saving others on the ill-fated 'Titanic,' but did not save himself. The proposed monument to Phillips' memory should undoubtedly be built strong and enduring, noting well the heroic actions of the daring young telegrapher. At one time in my career, I somewhat regretted that I did not quit the telegraph business when young, and embark in other lines, but now I am very thankful that I did not, and am becoming more in love and pleased with my profession as the years roll by. Yea, I am profoundly proud of it, seeing the wonderful achievements of the telegraph upon land and sea, adding blessings to mankind and promoting commerce and good-will among the nations of the earth. The telegraph operator has a noble calling, worthy of all acceptation. 'They are poor, yet making many rich.'

"The operator is 'unknown, and yet well known,' 'having nothing, yet possessing all things.' Since Morse invented the telegraph, and gave God the first honor, or first fruits; or, the first message: 'What Hath God Wrought,' the telegraph has been a blessing of the highest order to mankind."

The check has been forwarded to Mr. C. C. Galbraith, general manager United Wireless Telegraph Company, New York, who is chairman of the fund committee.

Two chimpanzees in the Central Park Zoological Garden, New York, which were formerly boon companions but are now in separate cages, telegraph to one another by knocking on an old iron pipe which runs along the rear of the cages.

CONSERVATION TALKS—IX.

BY P. KERR HIGGINS, OKLAHOMA CITY, OKLA.

(*Concluded.*)

One of the largest leaks in telegraph and telephone systems is in the plant department, that portion of it which maintains the toll or long distance lines. Not only does this waste involve loss of time, hence increased cost of maintenance, but also loss of revenue, during the period covered by the time the line or lines are out of service. It is surprising what little effort is made by district and local wire chiefs to keep in close touch with their toll sub-stations and very little care is taken in making tests on the lines in order to locate as near as possible the nature and place of trouble. Even in companies who boast of their fine system of supervision, the writer has found many violations of the rules.

It is true that in such companies, definite instructions are from time to time issued and excellent apparatus provided, but here the company stops; it utterly fails to see to it that the employes placed in charge fully understand the methods and faithfully apply them. Frequently the instructions issued are of the most complicated character and few if any fully understand them.

In many cases the employe is shown how to manipulate the keys or buttons and he does so automatically, but if any deviation takes place or any combination other than that known to him automatically takes place, he is lost; he does not want to expose his ignorance and takes chances.

In other companies no effort whatever is made to locate trouble and they go after such trouble on the "hit and miss" principle. Mostly miss. To the companies having wire chief instructions and apparatus I can only say that much money could be saved and a better knowledge might be had of such employes by a closer supervision of trip reports on toll and farmer lines. To those not having such instructions nor special apparatus, an examination of such trip reports and the lost circuit time due to "line out of order" (OD) conditions will probably prove in the necessity for having a central point to which all the small stations of that group would report every morning, so that the conditions of the lines and station apparatus may become a matter of record. Many telegrams and telephone mesages are lost due to failure "to raise" some small station or joint office. At such central points a daily log should be kept as shown in Fig. 1.

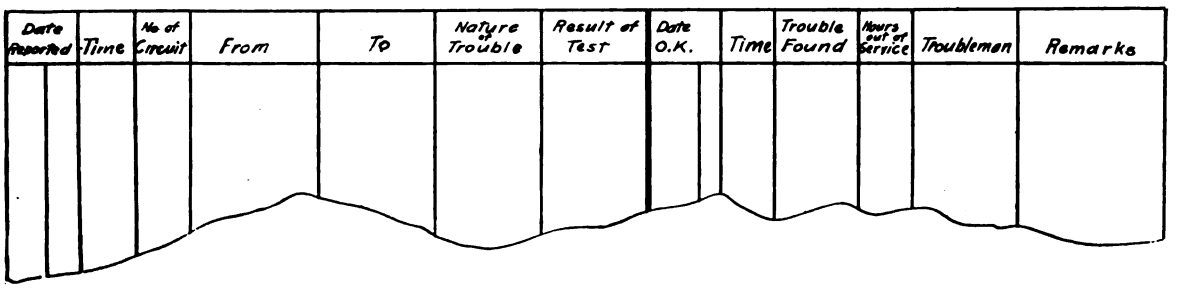

FIG. 1.—FORM OF LOG.

The Western Electric Company issue a bulletin known as No. 1012, which gives some very valuable information along this line in connection with a testing cabinet which it furnishes and which the writer has found extremely reliable and very simple in operation. There are many others on the market, but this bulletin is so clear, concise and simple that it is referred to as meeting many of the evils of the present "hit and miss" method.

To those who cannot afford to buy equipment of any kind, the following information may be valuable.

I desire to emphasize the fact that no matter how good the method is, no matter how efficient the equipment may be, or how simple it may be in construction it is absolutely of no value unless it is put in operation by brains. Do not forget this important fact.

The apparatus may be located either at or near the switchboard, or in the terminal room. No complicated mathematics are used and the reader is referred to the articles appearing in this magazine under the title "Course of Instruction in Elements of Technical Telegraphy," and which were begun October 16, 1911. The first articles deal with mathematics in simple, clear, concise form, and will apply to telephony as well as telegraphy, hence if the reader has any difficulty in following the rules and formulas used, he is urged to consult these articles, in fact it would be of great value to him to study these articles if for no other purpose than that of review.

I also desire to draw special attention to an explanation of "Ohm's law" as given on page 107 in the February 16 issue. The proper understanding of this law is absolutely necessary to all telephone and telegraph men who have to deal with plant questions, and it will certainly pay anyone to devote enough time to the study of this law as to make it fully understood.

The following material is necessary to fit up a testing outfit:

1. Dry battery of thirty volts (about 25 cells of good battery).

2. One Weston (10,000-ohm) or other good voltmeter; this must be of the very best type, otherwise results will be unsatisfactory.

3. Keys (lever or button), as shown in diagram. (Fig. 2.)

4. Testing and grounding cord.

Digitized by Google

5. Telephone set complete, including receiver and transmitter (desk, breast or wall type).
6. One hand generator (5-bar).
7. One test plug or shoe.
8. Two Frankel clips.
9. Punchings for terminals of wire.
10. One ringer (1000 or 1600 ohms).
11. One 600-ohm telegraph relay (not always necessary), but is found convenient in central battery systems to notify you when your troubleman is on line; a lamp can also be used for this purpose.
12. One two-microfarad condenser.
13. One cabinet.
14. Screws, etc.

In local battery systems a talking battery (three cells) will be required in addition to the testing battery. The testing battery should be connected in series to give thirty volts, and this voltage should be kept as constant as possible, so as to make the voltmeter readings correct. Always try the voltage of your battery before making any tests; this can be done by connecting (short circuiting) the tip and ring of the test plug together in any convenient manner and operate the voltmeter key, also the VS (voltmeter shunt) key when such is used. If in doing so the needle falls backs more than five points or begins to move back slowly after the keys are used a few seconds, your battery needs attention. This is done by testing each cell with a voltmeter and replacing the spent ones with good ones. Each cell should give one-and-a-quarter volts or more. Be careful not to place your testing battery too far—not over 20 feet—from the test cabinet and do not use smaller wire than No. 19 B. & S. rubber covered copper properly insulated. The zinc of the battery is the negative (—) and the carbon is the positive (+) pole of the battery. The following tests are possible with such a set.

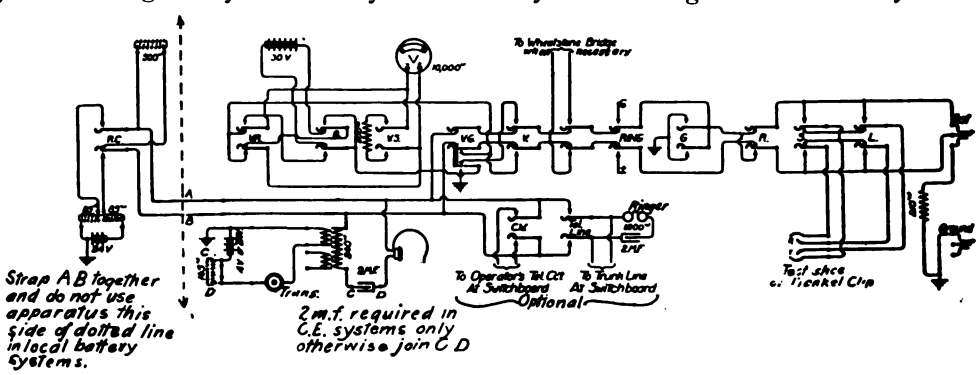
1. Talking on lines.
2. Ringing.
3. Test for continuity on closed circuits.
4. Test for ground.
5. Test for crosses with lines carrying current.
6. Test for crosses with lines not carrying current.
7. Test for short circuit.

key B the "kicks" can be repeated.

8. Test for open lines.

Whenever possible test direct to line, that is, with protector and exchange apparatus cut out; this simplifies the operation. Terminal apparatus should be so arranged as to permit the use of a two-way shoe being inserted, thus separating the outside and inside circuit and enabling the wire chief to test the outside or inside without taking out the test shoe. A 200-ohm non-inductive resistance coil is used as a shunt for the voltmeter and the operating of the (VS) voltmeter shunt key bridges this resistance around the voltmeter, thus reducing the deflection. When high resistance is tested the shunt need not be used, but should be used on low resistance.

The circuit shown in Fig. 2 is for a magneto, or local battery exchange, but can be modified to suit a central-battery system with very little change by adding a twenty-four-volt circuit, as shown at key RC, this supplies battery to the line for talking purposes; the manipulation of the keys for talking is not necessary in the local battery system. The circuit can easily be made suitable for selective party line ringing by duplicating the ringing keys of the switchboard on the test cabinet.



Strap A B together and do not use apparatus this side of dotted line in local battery systems.
2 m.f. required in C.E. systems only otherwise join C D
Optional

FIG. 2.—WIRE CHIEF'S TEST CIRCUIT.

CONTINUITY SETS. To ascertain if a metallic line (two wires clear of ground and forming one circuit) is continuous, that is not open, operate key V and if it is all right the needle will be deflected. If a previous test has been made, and the deflection noted with the line in good order, this deflection should now be shown; if less than the proper deflection some trouble exists, probably the resistance of a partial break, poor joint or connection. If the line is open, no deflection is shown. If testing a grounded line (single wire grounded at both ends) use key VG and not V, and if tip of the jack is connected to line, as it should be, use R with VG. In the case of central energy when condensers are used in conjunction with the sub-set, the deflection will be caused by what is known as the "condenser kick," that is needle is deflected momentarily and flies back.

This information is convenient in advising the wire chief that not only is the line clear, but the circuits as well up to and through the condenser at the telephone. In making such central energy tests use either V or VG and B. By working the key B the "kicks" can be repeated.

Digitized by Google

SHORT CIRCUITS. The test for a short circuit is similar to that for continuity, noting that the lower the resistance, the higher the deflection. Here we have to do a little figuring. The line resistance is found by dividing the difference between the test battery voltage and the voltmeter reading by the voltmeter reading and multiplying the result by 10.000 ohms = the resistance of the voltmeter.

Example: Battery reading, 30 volts.
Line test reading, 20 volts.
Then resistance of line equals

$$\frac{30-20}{20} \times 10{,}000 \text{ ohms} = 5000 \text{ ohms.}$$

By operating the VS key (shunt) the combined resistance (VM and shunt) is 196 ohms, instead of 10,000, hence the reading is smaller, but the same formula is applied, but using 196 instead of 10,000. The average wire chief will find it easier to test by using the voltmeter shunt key.

Great care must be exercised in testing lines to see that they are clear; that is, no other telephones thereon. If condensers are used in the telephones, then to all intents and purposes it may be considered a clear line.

GROUNDED LINE. Tests for grounds may be made on either side of the line (tip or sleeve) using VG and R for tip side only, VG tests the sleeve side. As in the short circuit tests, a clear line shows no deflection, or a very small one; the same applies to testing party lines as in testing metallic lines. When grounded party lines are being tested, use the same test as for short circuits, using the VS key.

CROSSES. These are of two kinds, one where the line is crossed with a "dead wire," that is one carrying no current, and the other a "live" wire, one carrying current, such for example as a cross with central energy lines, telegraph and electric light wires. In the latter case test as for a ground only use key B as well as VG and R. If the needle moves backward when B is used, operate VR; this is the voltmeter reverse key. Be careful in using the voltmeter on such tests and never use the shunt. It is always well to observe first what the voltage on such a line is before testing; if in excess of thirty volts do not attempt to test with the voltmeter as you may injure it.

TESTING TWO LINES CROSSED BUT NOT CARRYING CURRENT. Ground one line, in jack marked ground, and proceed to test the other line as though grounded. Be sure both lines are clear of ground before making this test. To get very accurate tests, a Wheatstone bridge must be used, but this is a subject in itself and will probably be taken up at another time. If needed now I am sure TELEGRAPH AND TELEPHONE AGE will be glad to sell a book devoted to this subject, by T. D. Lockwood, price $1.50, or one by N. H. Schneider at $1.00—both are good.

OPEN WIRES. These troubles are the most difficult to locate and even at best the test is only a guess and largely depends on the care and judgment of the tester. Operate key V then key B several times, noting the "throw" of the voltmeter needle. The greater the "throw," the greater the capacity. If VS is not used the capacity is proportional to the deflection. To determine the capacity between the ring side of the line and the ground, operate key B as before, but use VG instead of V, and to test the tip side use VG and R instead of V.

The capacity is then compared with the normal capacity of the line, or with another (clear) line of similar length. In testing MC lines use R instead of B; this makes the two readings in the same direction and twice the amount.

PRACTICE with such a set will enable the test clerk to make many other equally important tests. The tip is the farthest point, or ball, of the plug and the part coming in contact with the short spring of the jack; the ring of the plug is the second portion and connects with the long spring. Some plugs are divided into three parts, tip, ring, and sleeve and make contact in the jack in positions 1-2-3, 1 being farthest in the jack.

IMPORTANT. No wire chief can make successful tests who has not obtained conductivity, insulation and capacity tests of all lines under his care and supervision, when these lines are in good working order, and the records must be kept on file and checked up frequently. In this way not only can he scent trouble, but he can locate it more easily. Any deviation from such data means trouble. Note also that the loop (MC) resistance of any line decreases with the addition of more bridging telephones, hence the necessity for constantly reviewing data on such lines. Linemen should be required to report in on all cases of trouble and have the same properly tested out before returning to the office.

CONDUCTIVITY. Telephone companies suffer much from poor transmission, which can be avoided by keeping lines as near as possible up to the following standards, by watching for poor connections and poor joints by means of the test set.

Copper Wire (Hard Drawn).

	Weight per mile in lbs.	Resistance per mile in ohms
No. 8	264	3.31
No. 9	209.3	4.173
No. 10	166	5.264
No. 12	104.5	8.37

DIFFERENCE IN GAUGES USED. The N. B. S. is about two gauges smaller than B. & S. Only one gauge—B. W. G.—is used for iron wire.

Galvanized Iron Wire B. B. Grade.

	Lbs. per mile	Ohms resist. per mile
No. 9 B. W. G.	320	17.19
No. 10 B. W. G.	260	21.15
No. 12 B. W. G.	165	33.33
No. 14 B. W. G.	96	57.29

The resistance may be slightly lower in winter and slightly higher in summer.

Telegraph and Telephone Age Thirty Years Ago.

BY E. W. COLLINS, GENERAL SUPERINTENDENT POSTAL TELEGRAPH-CABLE COMPANY, CHICAGO, ILL.

Taltavall and Mitchell, thirty years ago, at a thrilling period in telegraph history launched upon a waiting world a very modest chronicler of events, known as THE TELEGRAPHER'S ADVOCATE, and while it was a precocious youngster, its most ardent admirers did not predict for it a long and happy life. After having passed safely through the measles, mumps and scarlet fever periods, however, it became strong and sturdy, and on June 1, 1912, it will celebrate its thirtieth birthday, after having changed its name twice and its clothes several times, to conform to new conditions, as they arose. The times were turbulent at its birth, and THE TELEGRAPHER'S ADVOCATE seemed to be an appropriate name. The craft, at that time, needed an advocate. Later, a long period of peace and contentment was ushered in, employer and employe became better acquainted, prosperity was everywhere, and a period of great telegraph development was the result. For some years during this period of development the name of the ADVOCATE was changed to TELEGRAPH AGE, and that cognomen was apropos for some years, until the telephone was developed from a toy to one of the greatest commercial and domestic requirements of the world, when the name was again changed from TELEGRAPH AGE to TELEGRAPH AND TELEPHONE AGE, which covers two of the giant industries of the world.

Thirty years is a long time! What wonderful advancement has been made, telegraphically and telephonically! What an era of achievement! Being absent from home and memoranda, I can only draw on my memory for events, and that is not very reliable. The first step forward—and one of the greatest—was the advent of the typewriter, which was a veritable boon to the public, but since the adoption of the typewriter, where are the beautiful chirographies of the past? Methinks I hear Tom Wheeler, Charlie Ganson, John Cronenberg, Ed. Hinman, and a great host of others, say: "Here is mine, unimpaired by time." Poor Cronenberg has gone to his long home, but think of the copies he used to make! When I was in St. Louis recently, I had the pleasure of seeing Tom Wheeler's copy, for the first time in thirty-eight years, and, although the old gentleman is struggling under a burden of years, his copy has not deteriorated a particle. It is the same "thing of beauty" it was when life was young and nerves were steel. In Detroit, recently, I found Charlie Ganson making those picture copies of his while his gray hairs smiled down upon his hand. Ed. Hinman? I don't know where he is, but I am ready to swear that he can still put the Lord's Prayer on a postal card so legibly that you would rather have it than a typewritten copy to transmit. We do not find the beautiful handwriting to be characteristic of the modern operator, because conditions have changed.

The perfection of quadruplex apparatus was the next great advance in telegraphy, followed closely by the use of the dynamo in telegraphic work as a substitute for the old Callaud battery, which was non-elastic, occupied valuable space, was never "on the job" when wanted, and had no reserve power.

Next was the wedding of the two systems, the telegraph and the telephone, both willing to live together and travel together on one wire and defy anybody to say which is the "better half." How wonderful are our electrical engineers, and how uncanny are some of the wonderful things they give to the world!

The wireless was the next step forward, and, while that system of signalling is still in its infancy, it is making a loud noise. Recent events on lakes and oceans have demonstrated its usefulness to mankind whether it finally becomes a dividend earner or not, and our hats should be taken off to Marconi and others whose perseverance in the face of discouraging obstacles has been wonderful.

You have confined me to 500 words with which to cover a period of thirty years, and because of the short time allotted me for the preparation of statistics, I have simply gone back in memory over the "path," stopped here and there to drop a tear over the grave of a boon companion who fell by the wayside, tired of his burden, and I come back from the fresh faces and sprightly forms of youth to clasp the hands of the dear old friends of today, friends who have labored with me, side by side, for over thirty years; friends whose grief was as poignant as my own when the hands of mutual friends ceased to copy and were folded forever.

We limp a little when we count up our years, and our hands cramp a little when we think of the Eitemillers and the "Patsy" Ayres who made it so interesting for us in the old days with that wonderful Morse of theirs; yea, even before the days of bonus, when there was no other incentive to speed than a desire to render a good day's work and—I nearly forgot to add—make the "other fellow" stay awake. How limber they were, and how they did like to keep things moving!

Before closing I wish to congratulate most heartily the editor and proprietor of TELEGRAPH AND TELEPHONE AGE, who has been on the alert for thirty years. He has kept pace with the best thought of the interests he has aimed to serve. He has given us an organ, the semi-monthly study of which has enabled us to keep in the front ranks of our profession, and, if we have failed, the responsibility for failure rests with us, for we must remember that:

"Every forehead which has been bathed
in glory was first bathed in sweat."

Wise Bank Robbers.—After taking the precaution to cut the telephone wires in order to prevent the spread of an alarm, robbers blew open the vault of a bank in Camden, Tenn., and secured about $7,000.

Mr. J. C. Browne, general supervisor of telegraph, Missouri Pacific Railway Company, St. Louis, Mo., writes: "In order to keep up to date in two ways, I am herewith renewing my subscription to TELEGRAPH AND TELEPHONE AGE."

The Morkrum Telegraph Printer.

As the Morkrum telegraph printers are now being introduced and through their performance attracting general attention, a description of the system will be of interest. The inventions involved in this system are the joint work of Mr. Chas. L. Krum, a mechanical engineer, and Mr. Howard L. Krum an electrical engineer, and the development of the system is due to Mr. Joy Morton, a capitalist of Chicago, the name Morkrum being a contraction of Morton-Krum.

The Morkrum printing telegraph is a direct acting keyboard system; that is, the operation of the keyboard at the sending end actuates the printing mechanism at the receiving end directly without any intermediate operations.

It is a page printer, using on the receiver all the ordinary telegraph forms without any special preparations, and on the home recorder a record of messages transmitted is recorded on a page-wide roll, both receiver and recorder giving visible writing.

Very early in the development of the system it was determined that upon the simplicity of the line currents used would depend the ability of a printer to operate successfully under the varying conditions of weather and line interference and that to meet these requirements it was essential that the current should be of a single strength and with no zero position. Accordingly it was made identical with the Morse polar duplex, securing all the reliability of that system, with its ability to work duplex successfully over long lines, and also making it possible to repeat through direct point repeaters.

The transmitted signal is divided into six time intervals. The negative pole of the battery is normally connected to the line between signals, and it is accordingly necessary that a signal be started by connecting the positive pole to the line.

Fig. 1 shows a signal in which current of positive polarity is sent to the line during all of the

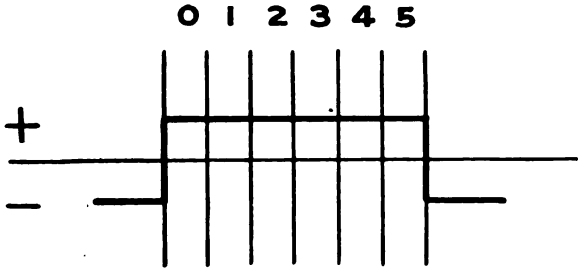

FIG. 1.

FIG. 1.—REPRESENTATION OF ONE SIGNAL.

six time intervals. The first interval is designated as O in the diagram, and is known as the starting interval. The selective signaling is accomplished by combinations of reversals of polarity of the current sent to the line during the five succeeding time intervals. This allows thirty-two selections to be made over the line, and by using a shift of the type wheel, fifty-three letters, figures and characters are printed.

This system of selective signaling is illustrated by Fig. 2, which shows the signals sent over the line for the word "The." The letter T is formed

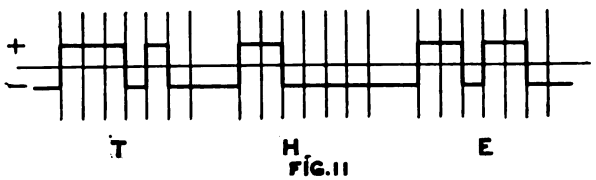

FIG. 2.—SIGNALS OF WORD "THE."

by reversing the polarity of the current sent to the line during the third and fifth intervals. In letter H the current is reversed during the second, third, fourth and fifth intervals, while in letter E the reversal takes place during the second and fifth intervals.

As in this system there is never to exceed three and an average of only two signaling currents sent to the line, for each letter, it is not necessary to transmit the signals at a high rate of speed, in order to obtain a free transmitting keyboard.

Fig. 3 shows the theory of the action of the receiver in selecting the different signals. The receiving mechanism is arranged to connect the

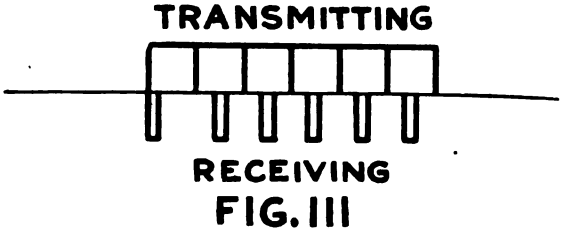

FIG. 3.—THEORY OF ACTION OF RECEIVER.

selective locks to the line relay for only a short portion of the duration of each time interval of the transmitting signal.

The system is not synchronous in the ordinary sense of the word, but is roughly isochronous; that is, the receiving mechanism is adjusted to run approximately the same speed as the transmitting mechanism, and a governing rheostat is provided to regulate the speed of the receiving mechanism, so that the relation of the received intervals to the transmitted intervals can be correctly adjusted. This is for the purpose of compensating for any difference in the voltages of the local power at the two ends. With this arrangement any difference in transmitting and receiving speed is not cumulative and allows of considerable distortion of the signals before the selection is interfered with, as it is only necessary that the interval of the receiving mechanism be somewhere within the limits of the corresponding transmitted signal.

The mechanism is divided into a number of elements, the functions of which and their relations to each other are best explained by reference to

Digitized by Google

Fig. 4, in which T is a motor driving transmitter and home recorder disks. R is a receiving bank of relays and A an auxiliary bank.

The combinations corresponding to the different signals are set up in five pole changers, in the keyboard, one for each of the five selective time intervals. The function of the transmitter disk is to connect these pole changers successively to the main line pole changer. As shown, the keyboard and transmitter control the action of the home recorder relay and the pole changer. The operation of the home recorder is accomplished selective in exactly the same manner as that of the printing mechanism at the far end.

On the relays the contacts correspond to the "marking" and "spacing" contacts of a Wheatstone relay, and are so designated. The marking contact point of the home recorded relay operates through a disk, which acts as a distributor and successively connects the selective lock relays in an auxiliary bank to the spacing contact of the home recorder relay. The spacing intervals of the signal operate the corresponding selective locks, while the marking intervals leave them unoperated. The lock relays in the auxiliary bank control the mechanism of the printer, the actual selection of the letter being accomplished in the printer.

The first four intervals control a mechanical selecting device, which interposes the proper stop pin in the path of the type-wheel arm, and the fifth interval governs the direction of rotation of the typewheel, and completes the operation of printing the lever.

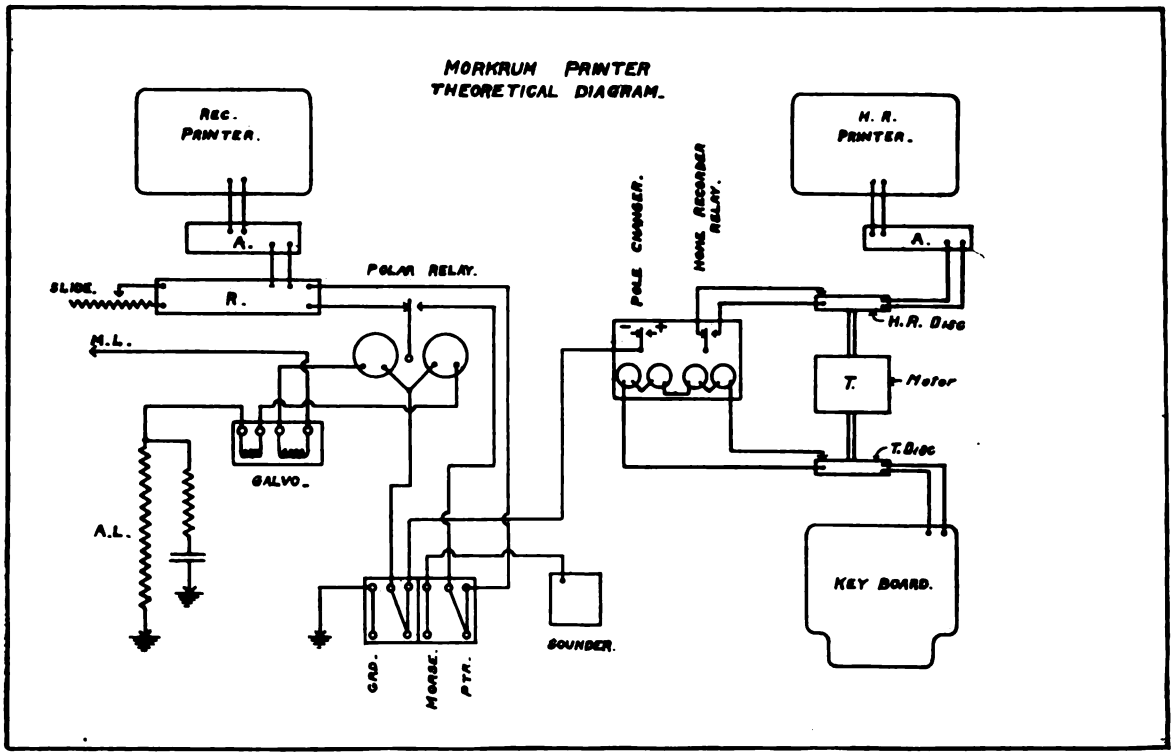

FIG. 4.—DIAGRAM OF CONNECTIONS OF APPARATUS.

FIG. 5.—TOP OF DUPLEX TABLE.

Digitized by Google

In a duplex set the contact points of the main line pole changer are connected to the two poles of the main line battery, while the tongue is connected through a ground switch to the split of the main line relay. After leaving the main line relay, one side passes through a differential galvanometer to the artificial line.

The contact points of the main line relay control the action of the receiver bank, auxiliary bank and receiving printer. A three-point switch is arranged so that the marking contact of the main line relay may be connected to a Morse sounder, if desired.

The receiver banks, auxiliary banks and printers used in the receiver and home recorder are identical and interchangeable; these, and also the transmitter and keyboard, are provided with slip connections so that any of them may be instantly removed and another element substituted.

The keyboard action is very light, requiring only a slight touch to start it, the stroke being completed by an electromagnet and it can be operated all day with much less fatigue than an ordinary typewriter. It also has a key lock which insures a complete signal being sent before another can be started.

FIG. 6.--KEYBOARD AND HOME RECORDER.

The Morkrum printers, working duplex, have a capacity of from 900 to 1100 messages in a nine-hour day, the capacity being largely dependent upon the operators. One circuit averaged 988 messages a day for a week, the best records being 1156 in a day, and in one direction 615 and 624 messages have been transmitted. One young lady operator in the New York office of the Postal Telegraph-Cable Company, sent 240 messages in three consecutive hours. If this pace could be kept up both ways for the nine hours it would carry 1440 messages over the line.

The Morkrum printers were first introduced in regular service by the Postal Telegraph-Cable Company, between New York and Boston, that circuit now having been in operation nearly two years. Since then these printers have been installed for the Postal Company on additional circuits between New York and Boston, New York and Philadelphia, New York and Washington, Philadelphia and Washington, Chicago and St. Louis, and in branch office work.

The Western Union Telegraph Company has several sets in operation between New York and Philadelphia, and is extending its use.

The Chicago, Burlington and Quincy Railroad was the first to introduce the Morkrum printers in railroad work, on a line from Chicago to Galesburg, and its use has since been extended on this road. The Lake Shore Railroad has a set between Cleveland and Toledo and the New York Central and Canadian Pacific roads have also arranged for its use.

Institute of Radio Engineers.

The Institute of Radio Engineers met at Columbia University, New York, June 3 at 8 p. m.

The committee on symbols and nomenclature will meet frequently during the summer months at the College of the City of New York, and will report at the next meeting of the Institute the first Monday in September. The members of this committee are: Mr. Fritz Lowenstein, Mr. G. W. Pickard, Mr. John Stone Stone, Dr. Oliver N. Goldsmith, Mr. John L. Hogan, Jr., Mr. R. A. Weagant and Mr. R. H. Marriott (ex-officio).

Mr. Lesh gave a very interesting talk on aeroplanes, in which he said that the noise of the engine is so great at present that it prevents the wireless operator from hearing signals. However, he believed this noise would be eliminated in time. He stated that more and more metal is used in aeroplanes. This metal can serve as one side of the open oscillating circuit of the radio telegraphic apparatus.

He further stated that there is little practical use for aeroplanes except for war scouting and to make them very useful in this service they should be equipped with wireless so they can continually report to headquarters, because it is always a question whether or not they will ever get back to headquarters.

Bust of Lord Kelvin.—A marble bust of the late Lord Kelvin was presented to the Institution of Electrical Engineers, London, by Lady Kelvin, on May 16. The presentation address was made by Sir W. H. Preece. Lord Kelvin, who is better known to the older generation of telegraphers as Sir William Thomson, made many important inventions in submarine and aerial telegraphy, and at the time of his death was regarded as one of the leading scientists in the world.

Mr. A. B. Cowan, district commercial superintendent of the Western Union Telegraph Company, Chicago, Ill., writes: "I enclose check for renewal of my subscription to TELEGRAPH AND TELEPHONE AGE. We cannot be up-to-date without it."

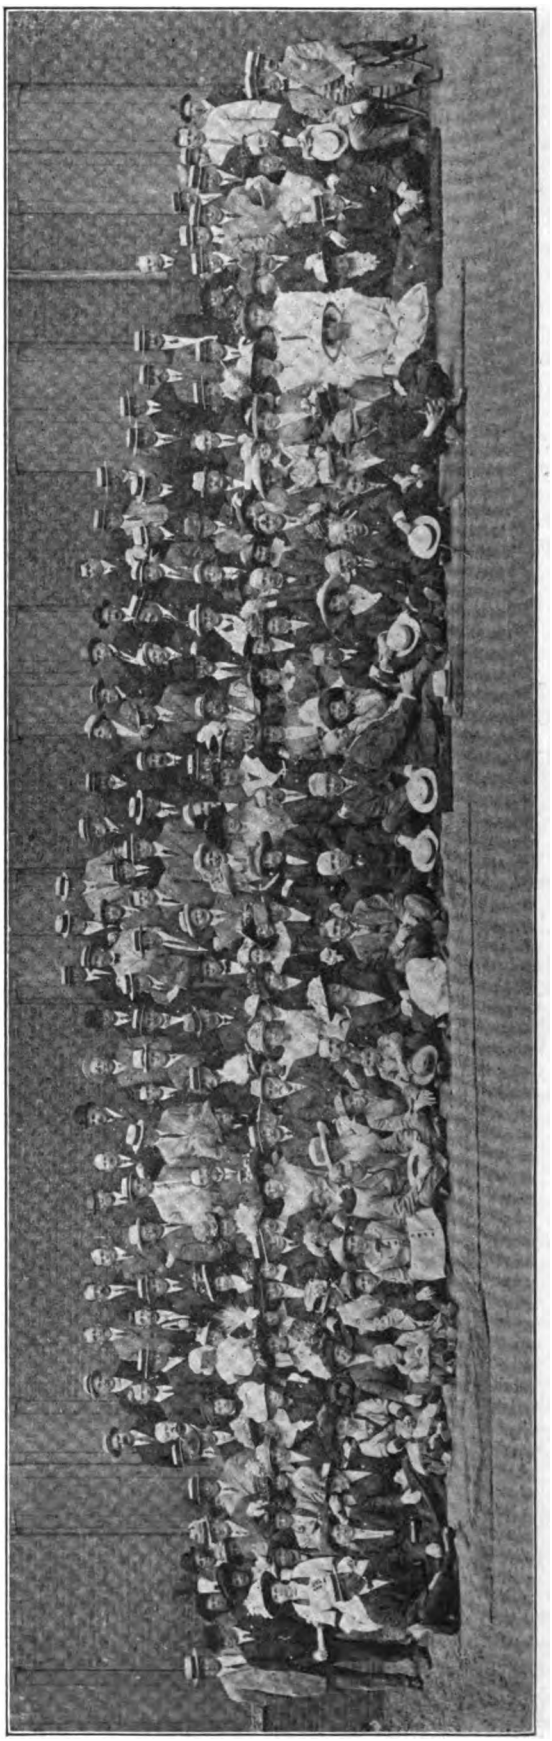
Digitized by Google

Vacuum Lightning Arresters.—The United States Electric Company has just issued a second edition of its Bulletin 301 devoted to vacuum lightning arresters. The first issue of this bulletin was regarded as one of the best short treatises available on the construction and use of lightning arresters and the general subject of the protection of telegraph and telephone apparatus from high potential discharges. The second edition describes also a new form of unit mounting in which a wood base is used in place of the porcelain and metal base and mounting, and this new form has found general favor, particularly in signaling equipment. The diagrams include various methods of protecting telephone equipment, test offices and submarine cable and the bulletin is especially timely at the opening of the season when damage from lightning may be apprehended.

Western Electric's April Business.—The total of goods billed out during April by the Western Electric Company shows an increase of 17 per cent. over the total for April, 1911. March ran about even with the preceding March, so that the first four months of 1912 are about 1½ per cent. ahead of the same four months in 1911. April's gain is looked upon by the company's officials as somewhat extra-normal and due to several special conditions. It indicates an increase in the year's total business which later months, it is believed, will not sustain. Those close to the company say that if 1912 shows as good business as last year, when sales totalled $66,000,000, they will be well satisfied with the result. Foreign business was an important contributing factor to the April improvement.

Anniversary of the Telegraph.—May 27 was the sixty-eighth anniversary of the transmission of the first message over the Morse telegraph when the historic message, "What Hath God Wrought," was transmitted. The telegraph received instant recognition, and two days later, May 29, 1844, the news of the nomination of James K. Polk for the presidency was telegraphed from the Democratic convention at Baltimore and was announced on the floor of Congress in Washington before the cheers for Polk had died away in the convention hall.

Mr. W. H. Allen, Washington, D. C., writes: "In renewing my subscription, I desire to pay tribute to the surpassing excellencies of the AGE. It is not easy to understand how anybody connected with the telegraph business would want to get along without it, and it is none the less valuable to those now engaged in other pursuits, as enabling them to keep informed on the vast progress making in their former vocation. Even the obituary notices are well worth having, as chronicling the passing of old friends and associates, calling up fond memories of pleasant happenings and kindnesses of by-gone years. Undoubtedly the AGE is indispensable."



RAILWAY TELEGRAPH SUPERINTENDENTS AND PARTY AT EDISON WORKS, WEST ORANGE, N. J., JUNE 7.

Construction Materials and Methods.*

BY R. E. CHETWOOD, ENGINEER OF CONSTRUCTION, WESTERN UNION TELEGRAPH COMPANY, NEW YORK.

The appraisal of the plant of the Western Union Telegraph Company made in the year 1910 by the engineering firm of Westinghouse, Church, Kerr & Company showed that the largest percentage of the telegraph company's investment was in its outside plant, consisting of pole lines, wires, conduits and cables. As the largest part of the telegraph company's investment is in this type of plant, it is, of course, very necessary and advisable that the construction of the outside plant should be of proper character and economical in cost.
